REQUEST FOR EX PARTE REEXAMINATION TRANSMITTAL FORM

Address to:
Mail Stop Ex Parte Reexam
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Attorney Docket No.: 24567-0002RX1

Date: April 24, 2009

1. ☒ This is a request for *ex parte* reexamination pursuant to 37 CFR 1.510 of patent number 5,809,336 issued September 15, 1998. The request is made by:

☐ patent owner.
☒ third party requester.
2. ☒ The name and address of the person requesting reexamination is:

Fish & Richardson, P.C.
3200 RBC Plaza, 60 South Sixth Street
Minneapolis, MN 55402
3. ☐ a. A check in the amount of \$ _____ is enclosed to cover the reexamination fee, 37 CFR 1.20(c)(1);
☒ b. The Director is hereby authorized to charge the fee as set forth in 37 CFR 1.20(c)(1) to Deposit Account No. 06-1050; or
☐ c. Payment by credit card. Form PTO-2038 is attached.
4. ☒ Any refund should be made by ☐ check or ☒ credit to Deposit Account No. 06-1050 37 CFR 1.26(c). If payment is made by credit card, refund must be to credit card account.
5. ☒ A copy of the patent to be reexamined having a double column format on one side of a separate paper is enclosed. 37 CFR 1.510(b)(4)
6. ☐ CD-ROM or CD-R in duplicate, Computer Program (Appendix) or large table
☐ Landscape Table on CD
7. ☐ Nucleotide and/or Amino Acid Sequence Submission
If applicable, items a. - c. are required.
 - a. ☐ Computer Readable Form (CRF)
 - b. Specification Sequence Listing on:
 - i. ☐ CD-ROM (2 copies) or CD-R (2 copies); or
 - ii. ☐ paper
 - c. ☐ Statements verifying identity of above copies
8. ☐ A copy of any disclaimer, certificate of correction or reexamination certificate issued in the patent is included.
9. ☒ Reexamination of claim(s) 1-10 is requested.
10. ☒ A copy of every patent or printed publication relied upon is submitted herewith including a listing thereof on Form PTO/SB/08, PTO-1449, or equivalent.
11. ☐ An English language translation of all necessary and pertinent non-English language patents and/or printed publications is included.

[Page 1 of 2]

This collection of information is required by 37 CFR 1.510. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.11 and 1.14. This collection is estimated to take 2 hours to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Mail Stop Ex Parte Reexam, Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.

Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number.

12. ☒ The attached detailed request includes at least the following items:
- a. A statement identifying each substantial new question of patentability based on prior patents and printed publications. 37 CFR 1.510(b)(1)
 - b. An identification of every claim for which reexamination is requested, and a detailed explanation of the pertinency and manner of applying the cited art to every claim for which reexamination is requested. 37 CFR 1.510(b)(2)
13. ☐ A proposed amendment is included (only where the patent owner is the requester). 37 CFR 1.510(e)
14. ☒ a. It is certified that a copy of this request (if filed by other than the patent owner) has been served in its entirety on the patent owner as provided in 37 CFR 1.33(c).
The name and address of the party served and the date of service are:
Larry E. Henneman, Jr., Reg. No. 41,063
Henneman & Associates, PLC
714 W. Michigan Avenue, Three Rivers, MI 49093
Date of Service: April 24, 2009; or
☐ b. A duplicate copy is enclosed since service on patent owner was not possible.

15. Correspondence Address: Direct all communication about the reexamination to:

☒ The address associated with Customer Number: 21691

OR

☒ Firm or Individual Name Greg H. Gardella, Fish & Richardson P.C.

Address

60 South Sixth Street, 3200 RBC Plaza

Privacy Act Statement

The **Privacy Act of 1974 (P.L. 93-579)** requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether disclosure of these records is required by the Freedom of Information Act.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (*i.e.*, GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspection or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

APPENDICES

APPENDIX A - U.S. Patent No. 5,809,336 to Moore et al.

APPENDIX B - Relevant portions of the '336 patent file history.

APPENDIX C - Relevant portions of the merged '336 reexamination (Control No. 90/008,474)

APPENDIX D - U.S. Patent No. 4,853,841 to Richter.

APPENDIX E - U.S. Patent No. 4,348,743 to Dozier.

APPENDIX F - Mostek, 3870 Microcomputer Data Book (Feb. 1981).

APPENDIX G - U.S. Patent No. 4,931,748 to McDermott et al.

APPENDIX H - U.S. Patent No. 4,766,567 to Kato.

APPENDIX I - U.S. Patent No. 4,691,124 to Ledzius et al.

APPENDIX J - IC Master 1980 (United Technical Publications) (1980)

I. INTRODUCTION

The independent claims of the '336 patent are directed to a microprocessor system that includes a ring oscillator for a system clock and a central processing unit (CPU) on a single integrated circuit. The independent claims require the ring oscillator and CPU to be constructed of the same process technology so that the speed of the ring oscillator and the CPU vary together. The independent claims further require an on-chip input/output (I/O) interface, to which a second clock independent of the ring oscillator is connected.

During prosecution of the underlying application the Patent Owner amended the independent claims in response to a prior art rejection to recite the second clock independent of the variable speed system clock for clocking the I/O interface. A summary of an examiner interview conducted on April 23, 1998 indicated that the claims were allowed because the Examiner believed that the prior art contained no disclosure or suggestion of clocking an I/O interface with a second clock independent of the variable speed system clock.

The Mostek reference (*Appendix F*), which was not before the original Examiner, discloses precisely this feature. Mostek describes a single semiconductor chip containing a main control logic that is clocked by a variable frequency internal oscillator. The chip includes a serial I/O port that is clocked by a fixed frequency external clock that is independent of the internal oscillator. (*Appendix F, pages III-105 and III-114 to III-115*) Furthermore, the Mostek reference teaches every other feature recited in each of the independent claims of the '336 patent with the sole exception that the Mostek reference does not explicitly state that the on-chip "variable speed oscillator" is a "ring oscillator" as recited in the claims. However, according to the Patent Owner, a variable speed oscillator qualifies as a ring oscillator as that term is used in the '336 patent. In connection with recent attempts to persuade major companies to take licenses under the '336 patent the Patent Owner has repeatedly asserted in writing that "industry best practices dictate" that clock generators include ring oscillators. If the Office accepts this premise, then the Mostek reference would be understood by one skilled in the art as disclosing a ring oscillator given that commercial clock generators have not substantially changed in material respect since the date of the Mostek reference. If interpreted in this way, the Mostek reference anticipates claims 1-7, 9, and 10 of the '336 patent.

In any case, one skilled in the art would have found apparent reasons to combine the Mostek reference with the ring oscillator system clock taught by the Kato reference (*Appendix H*). One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Mostek's variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (*Appendix H, col. 11, lines 2-7*). As explained in more detail below, claims 1-10 of the '336 patent are at a minimum rendered obvious by Mostek in view of Kato.

Moreover, two additional references that were not before the Examiner – Richter (*Appendix D*) and Dozier (*Appendix E*) – each disclose the second, independent I/O clock thought to be missing from the prior art. Richter teaches clocking an on-chip I/O port with an oscillator independent of a system clock. Richter teaches a microprocessor system having a serial interface which is connected by an input/output port to a signal line of a serial bus system. Richter teaches a signal "ftakt" for clocking the serial I/O port of the microprocessor that is independent of the CPU clock: "the data transmission of the serial interface is supplied with the clock frequency signal 'ftakt', and the microprocessor of the microprocessor system 2 is equipped with its own system clock generator." (*Appendix D, col. 4, lines 34-43 and 58-62*) Richter describes the system clock of the microprocessor as a "separate system clock generator for the microprocessor" that is independent of the I/O clock signal. (*Appendix D, col. 4, lines 36-47*) The remaining features recited in the claims of the '336 patent are plainly disclosed in Richter. Dozier also discloses the above described features of the claims of the '336 patent. Both Richter and Dozier, alone or in combination with other references, at a minimum render obvious all claims of the '336 patent (i.e. claims 1-10) as explained in detail in the claim charts set forth below.

The foregoing questions of patentability are new even with respect to the reexamination requests previously filed against the '336 patent. Neither the Richter reference (*Appendix D*) nor the Dozier reference (*Appendix E*) were before the examiner during the original examination of the '336 patent and are not currently before the examiner in the pending merged reexamination proceeding (*Reexamination Control Number 90/008,306*). As to the Mostek reference, the arguments presented herein are substantially different than those presented in the reexamination request filed by the Public Patent Foundation on January 30, 2007. For example, that earlier request did not argue that the Mostek reference anticipates any claim of the '336 patent. The

Mostek reference has not been relied upon to support a rejection in the pending reexamination proceedings (and as to the underlying application the Mostek reference was not of record).

II. CLAIMS FOR WHICH REEXAMINATION IS REQUESTED

Reexamination is requested for all claims (i.e., claims 1-10) of the '336 patent in view of the publications discussed below. A copy of the '336 patent (including a certificate of correction) is attached as Appendix A of this document, and copies of the relevant portions of the '336 patent prosecution history are attached as Appendix B.

III. PATENTS AND PRINTED PUBLICATIONS PRESENTED TO SHOW SUBSTANTIAL NEW QUESTIONS OF PATENTABILITY

1. U.S. Patent No. 4,853,841 to Richter (hereinafter "Richter"), attached as Appendix D.
2. U.S. Patent No. 4,348,743 to Dozier (hereinafter "Dozier"), attached as Appendix E.
3. Mostek, 3870 Microcomputer Data Book (Feb. 1981) (hereinafter "Mostek") attached as Appendix F.
4. U.S. Patent No. 4,931,748 to McDermott et al (hereinafter "McDermott") attached as Appendix G.
5. U.S. Patent No. 4,766,567 to Kato (hereinafter "Kato") attached as Appendix H.
6. U.S. Patent No. 4,691,124 to Ledzius et al (hereinafter "Ledzius") attached as Appendix I.
7. IC Master 1980 (United Technical Publications) (1980) (hereinafter "IC Master") attached as Appendix J.

It is believed that the references in Appendices D-J were not before the Examiner during prosecution of the '336 patent. Further, it is believed that the references in Appendices D, E, and G are not before the Examiner in the below described reexaminations of the '336 patent. For convenience, the aforementioned references are cited on the attached Form PTO-1449.

IV. CO-PENDING PROSECUTION AND LITIGATION

Requester believes that the '336 patent has not yet been adjudged invalid or unenforceable. Three reexaminations of the '336 patent, control numbers 90/008,237, 90/008,306, and 90/008,474, have been merged and are ongoing as of this request's filing date. Requester is aware of several pending lawsuits involving the '336 patent:

- Acer, Inc. et al. v. Technology Properties Limited et al., CV 08-00877 HRL, Filed Feb. 8, 2008 (N.D. Cal.)
- HTC Corp. et al. v. Technology Properties Limited et al., CV 08-00882 JL, Filed Feb. 8, 2008 (N.D. Cal.)
- BARCO v. Technology Properties Limited et al., CV 08-05398, Filed Dec. 1, 2008 (N.D. Cal.)

V. THE PROSECUTION HISTORY OF THE '336 PATENT

The application that matured into the '336 patent was filed on June 7, 1995 as a division of U.S. Patent No. 5,440,749 which itself was filed on August 3, 1989. The '336 application included 70 claims, although all but six were immediately cancelled. Claim 19, the only claim to survive the entire prosecution, eventually became Claim 1 of the '336 patent and originally read:

A microprocessor system, comprising a central processing unit and a ring counter variable speed system clock connected to said central processing unit, said central processing unit and said ring counter variable speed system clock being provided in a single integrated circuit.

(Appendix B, Application, June 6, 1995, original page 68).

During examination of the '336 application, the Examiner issued four office actions and the Applicant amended the claims in response to each. The Examiner rejected the independent claims after each subsequent amendment by the Applicant. After the fourth office action, an Examiner interview was held on April 23, 1998. During the interview, the Examiner proposed amendment of original dependent claims 20, 66, 75, and 79 and indicated that the amended claims 20, 66, 75, and 79 would be allowable if rewritten in independent form. *(Appendix B, Applicant Remarks, April 24, 1998; Examiner Interview Summary Record, May 13, 1998)* Each of original claims 20, 66, 75, and 79 included a limitation directed toward an input/output interface that is connected to a second clock which is independent of the ring oscillator. The Applicant accordingly amended the independent claims to include the limitations of original

dependent claims 20, 66, 75, and 79. Namely, the independent claims were amended to recite an on-chip I/O interface and a second I/O clock that is independent of the ring oscillator. For example, claim 19 was amended:

A microprocessor system, comprising a single integrated circuit including a central processing unit and an entire ring oscillator variable speed system clock in said single integrated circuit and connected to said central processing unit for clocking said central processing unit, said central processing unit and said ring oscillator variable speed system clock each including a plurality of electronic devices correspondingly constructed of the same process technology with corresponding manufacturing variations, a processing frequency capability of said central processing unit and of said ring oscillator variable speed system clock varying together due to said manufacturing variations and due to at least operating voltage and temperature of said single integrated circuit; an on-chip input/output interface connected to exchange coupling control signals, addresses and data with said central processing unit; and a second clock independent of said ring oscillator variable speed system clock connected to said input/output interface.

(*Appendix B, Applicant Remarks, April 24, 1998 at Claim 19*). The application was subsequently allowed.

Accordingly, the '336 patent was allowed principally because the prior art before the Examiner was believed not to disclose an integrated circuit with an on-chip I/O interface clocked by a second clock independent of the variable speed system clock.

VI. POSITIONS TAKEN BY PATENT OWNER THAT ARE MATERIAL TO PATENTABILITY

The Patent Owner has sent numerous communications to third parties in an attempt to solicit licenses under the '336 patent. The communications generally include claim charts stamped "confidential" that purport to show the correspondence between the third party processor systems and the claims of '336 patent.

In these claim charts the Patent Owner has taken various positions to the effect that any processors having certain features would necessarily have other features recited in the claims of the '336 patent. These are particularly relevant to the Office's assessment of how one skilled in the art would interpret various prior art references. In particular, if the Patent Owner's assertions are accepted, then various prior art references explicitly teaching certain features would be understood by one skilled in the art as implicitly disclosing other features.

Where the Patent Owner has taken a position in third party correspondence which would dictate a finding that a certain feature would be understood to be present in a prior art system, that fact is noted in the claim charts set forth below.

The Office is encouraged to request from the Patent Owner the claim charts and related third party communications concerning the '336 patent under Rule 105.¹ Requester understands that scores of substantially similar claim charts have been sent to various companies throughout the semiconductor and other industries.

The Requester notes that the functionality of prior art processors are the same in material respect as commercial processors referred to by the Patent Owner in the above mentioned communications to third parties (e.g., with regard to on-chip oscillators, serial I/O ports, etc.). For example, the Mostek 3870 family of processors of the 1980's included serial I/O ports with independent I/O clocks for conducting asynchronous I/O functions. (*See, e.g., Mostek, 3870 Microcomputer Data Book (Feb. 1981) at page III-105*). Therefore, if the Patent Owner's assertions are true today as to commercial processors, then they are also true as to the prior art processors.

VII. QUESTIONS OF PATENTABILITY PRESENTED HEREIN ARE NEW RELATIVE TO THE PENDING REEXAMINATION PROCEEDINGS

The prior art references provided in this request present a substantial new question of patentability as to claims 1-10 of the '336 patent even with respect to the reexamination requests previously filed against the '336 patent. Both the Richter reference (*Appendix D*) and the Dozier reference (*Appendix E*) were not before the examiner during the original examination of the '336

¹ Requester submits that the Office is empowered to request this information under Rule 105, which provides in pertinent part:

(a) (1) In the course of examining or treating a matter in a pending or abandoned application filed under 35 U.S.C. 111 or 371 (including a reissue application), in a patent, or in a reexamination proceeding, the examiner or other Office employee may require the submission, from individuals identified under § 1.56(c), or any assignee, of such information as may be reasonably necessary to properly examine or treat the matter, for example:

(viii) Technical information known to applicant. Technical information known to applicant concerning the related art, the disclosure, the claimed subject matter, other factual information pertinent to patentability, or concerning the accuracy of the examiner's stated interpretation of such items.

The assertions of infringement made by Patent Owner explicitly contain a technical assessment of architecture defining a ring oscillator, a second clock independent of the ring oscillator, and whether the ring oscillator and a CPU clocked by the ring oscillator inherently include a plurality of devices and whether the frequency of the ring oscillator and the speed of the CPU would vary together due to manufacturing variations. Requestor respectfully submits that this information is clearly "factual information pertinent to patentability." The Office is accordingly urged to request that the Patent Owner produce claim charts and other materials submitted to third parties sufficient to demonstrate the technical and claim construction positions taken by the Patent Owner.

patent and are not currently before the examiner in the pending merged reexamination proceeding (*Reexamination Control Number 90/008,306*). As to the Mostek reference, the arguments presented herein are substantially different than those presented in the reexamination request filed by the Public Patent Foundation on January 30, 2007. For example, that earlier request did not argue that the Mostek reference anticipates any claim of the '336 patent. Furthermore, the Mostek reference has never been adopted for use in a rejection during the pending reexamination proceedings. The following sections set forth in detail the correspondence between claims 1-10 and the Mostek, Richter, and Dozier references.

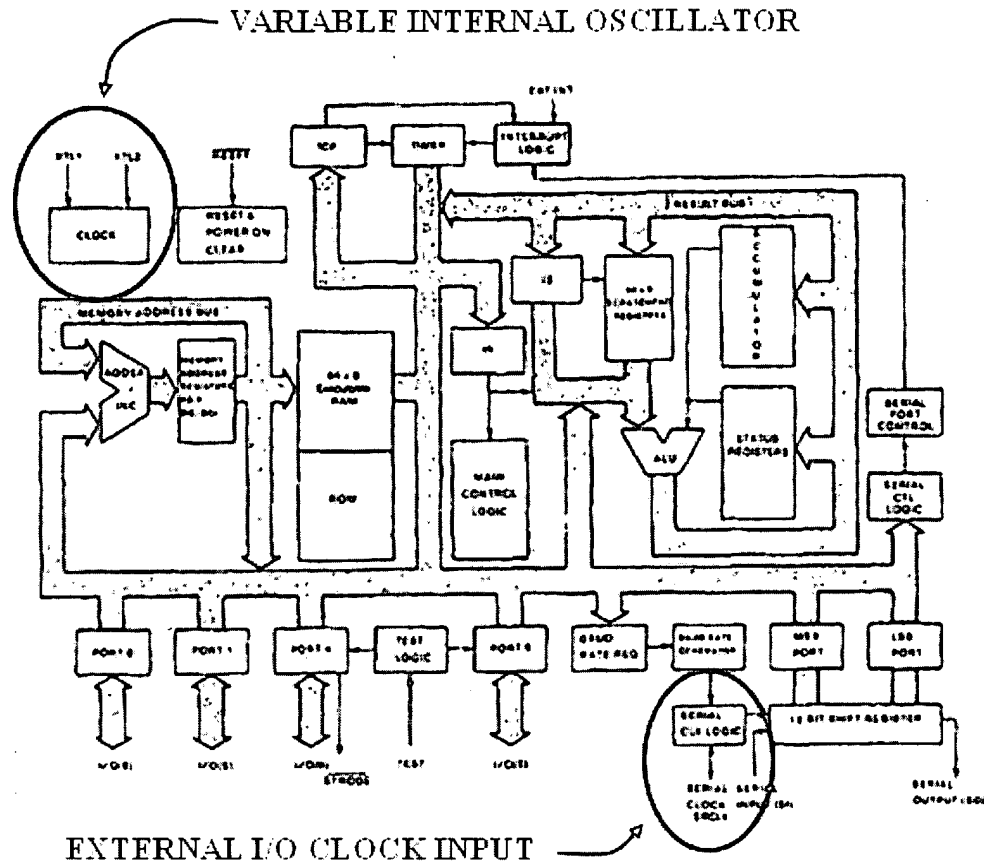

VIII. THE MOSTEK REFERENCE ANTICIPATES OR RENDERS OBVIOUS CLAIMS 1-10 OF THE '336 PATENT

The prior art references provided in this request raise substantial new questions of patentability as to claims 1-10 of the '336 patent. Specifically, claims 1-7, 9, and 10 are anticipated by the Mostek reference and additionally all claims (e.g. claims 1-10) are rendered obvious by Mostek in light of the Kato reference.

A. Summary of the Teachings of the Mostek Reference

The Mostek, 3870 Microcomputer Data Book (Feb. 1981) ("Mostek") teaches the MK3873, which the data book describes as a single semiconductor chip containing a main control logic that is clocked by a variable internal oscillator. The MK3873 single semiconductor chip also includes a serial I/O port that can be clocked by a fixed frequency, external clock that is independent of the internal oscillator.

More specifically, Mostek teaches a "single chip microcomputer" that includes an "on-chip oscillator circuit which provides an internal clock." (*Appendix F, pages III-114 to III-115*). The frequency of the on-chip oscillator, and thus the processing speed of the main control logic, varies in response to temperature and Vcc variations, as one skilled in the art would understand from reference to other data books describing the MK3873 microprocessor. (*Appendix J, Fig. 3; pages 2019 and 2024-2026*).

(Appendix F, Figure 1 at page III-103).

Mostek teaches a serial I/O port that is clocked by an external clock independent of the on-chip oscillator circuit. (*Appendix F, pages III-105 and III-114 to III-115*). The external clock may use a crystal to provide a fixed frequency signal. (*Appendix F, pages III-109 to III-110*). Additionally, the serial port is “very flexible so that it could be used . . . as an interface to . . . serial memory devices.” (*Appendix F, page III-102, col. 1*).

B. The Mostek Reference Anticipates Claims 1-7, 9 and 10 of the '336 Patent

The '336 patent claims the same functionality described above in connection with the Mostek reference. The patent claims a microprocessor system comprising a single integrated circuit that includes a ring oscillator and a central processing unit (CPU), where the ring oscillator clocks the CPU. (*Appendix A, Claim 1*). The claimed ring oscillator and CPU include a plurality of electronic devices that are constructed of the same process technology so that the frequency of the central processing unit and the speed of the ring oscillator vary together.

(*Appendix A, Claim 1*). The claimed integrated circuit also includes an on-chip I/O interface, to which a second clock independent of the ring oscillator is connected. (*Appendix A, Claim 1*).

This is precisely the functionality taught by the Mostek reference. Mostek teaches a microcomputer implemented on a single chip that includes a main control logic clocked by an internal oscillator, where the frequency of the main control logic and the internal oscillator vary together due to variations in at least temperature and Vcc. The Patent Owner has asserted in correspondence with third parties that an internal oscillator indicates the presence of a ring oscillator and that a CPU and an on-chip oscillator inherently include a plurality of devices and are constructed of the same process technology. Significantly, Mostek discloses a serial input/output port that is clocked by an external clock that is independent of the variable speed oscillator.

Detailed correspondence between the Mostek reference and claims 1-7, 9, and 10 of the '336 patent is shown in the claim chart in section D below.

C. The Mostek Reference, in Light of the Kato Reference, Renders Obvious Claims 1-10 of the '336 Patent

In addition to Mostek's anticipation of the '336 patent as described above, the Mostek reference, when viewed in light of the Kato reference, further renders obvious several of the limitations already taught by Mostek.

It would have been obvious for one skilled in the art to modify the teachings of Mostek so that a ring oscillator was implemented as Mostek's disclosed variable speed oscillator. This is because the Kato reference discloses a "one-chip semiconductor device" (*Appendix H, col. 1, lines 6-9*) that is clocked by a ring oscillator because the clock signal "need not have a very accurate frequency." (*Appendix H, col. 10, line 64 to col. 11, line 7*). The ring oscillator's "output frequency lowers in proportion to the speed of the data processing circuit which is lowered due to the drop of power supply voltage." (*Appendix H, col. 11, lines 1-5*).

One skilled in the art would have seen an apparent reason to implement the variable speed oscillator disclosed in Mostek with Kato's ring oscillator, namely because the family of chips described by the Mostek data book also operate from their internal oscillators when "timing is not critical" and a ring oscillator is an obvious selection for an internal oscillator. (*Appendix J, page 2019*). One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Mostek's variable oscillator to reduce power consumption during

periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (*Appendix H, col. 11, lines 2-7*). Kato additionally teaches a second clock connected to the I/O port which operates synchronously relative to the ring oscillator as recited in claim 8 of the '336 patent. Therefore, claims 1-10 of the '336 patent are at a minimum rendered obvious by Mostek in view of Kato.

D. Claim Chart Setting Forth the Correspondence Between the Mostek Reference and Claims 1-10 of the '336 Patent

As described herein, the Mostek reference (*Appendix F*) taken alone or in combination with the Kato reference, raises substantial new questions of patentability for all claims of the '336 patent. The following claim chart demonstrates that all elements in claims 1-10 are anticipated or rendered obvious by the Mostek reference.

Claim Limitation	Teaching of the Mostek Reference
Claim 1	
1. A microprocessor system, comprising a single integrated circuit	This feature is taught by Mostek, 3870 Microcomputer Data Book (Feb. 1981) ("Mostek"). The Mostek reference discloses a " <i>single chip microcomputer</i> " with features including a main control logic, executable RAM, ROM, and a serial input/output port. (<i>Appendix F, pages III-102 and III-103</i>).

<p>Claim Limitation</p>	<p style="text-align: center;">Teaching of the Mostek Reference</p> <p style="text-align: center;">(Appendix F, Figure 1 at page III-103).</p>
<p>including a central processing unit and</p>	<p>Mostek teaches a central processing unit, as indicated by discussion of the microcomputer's "CPU over head," "CPU instructions," "CPU Registers," and "processing . . . that occupies the CPU." (<i>Appendix F, pages III-102, III-104, and VI-8</i>). One skilled in the art would understand Mostek's Main Control Logic to disclose the recited CPU as the Main Control Logic "provides the necessary control gating signals to all circuit elements," as noted by another data book describing the 3870 family of chips (<i>Appendix J, page 2019</i>). The MK3873 described by Mostek includes architecture that is "identical to that of the rest of the devices in the 3870 family with the exception of the serial port logic." (<i>Appendix F, page III-102</i>).</p>
<p>an entire ring oscillator variable speed system clock in said single integrated circuit and connected to said central processing unit for clocking said central processing unit,</p>	<p>Mostek teaches an "on-chip oscillator circuit which provides an internal clock." (<i>Appendix F, pages III-114 to III-115</i>). Additionally, Mostek states that "the architecture of the MK3873 is identical to that of the rest of the devices in the 3870 family with the exception of the serial port logic." (<i>Appendix F, page III-102</i>). One skilled in the art would know that the 3870 family of chips contain variable internal oscillators as described by the IC Master databook (IC Master 1980 (United Technical Publications) (1980)). For example, the IC Master databook states that "<u>If timing is not critical</u>, the F3870 will operate from its internal oscillator with no external components" (<i>Appendix J, page 2019</i>) (<i>emphasis added</i>). The internal oscillators of the 3870 family chips are disclosed to vary in frequency from</p>

Claim Limitation

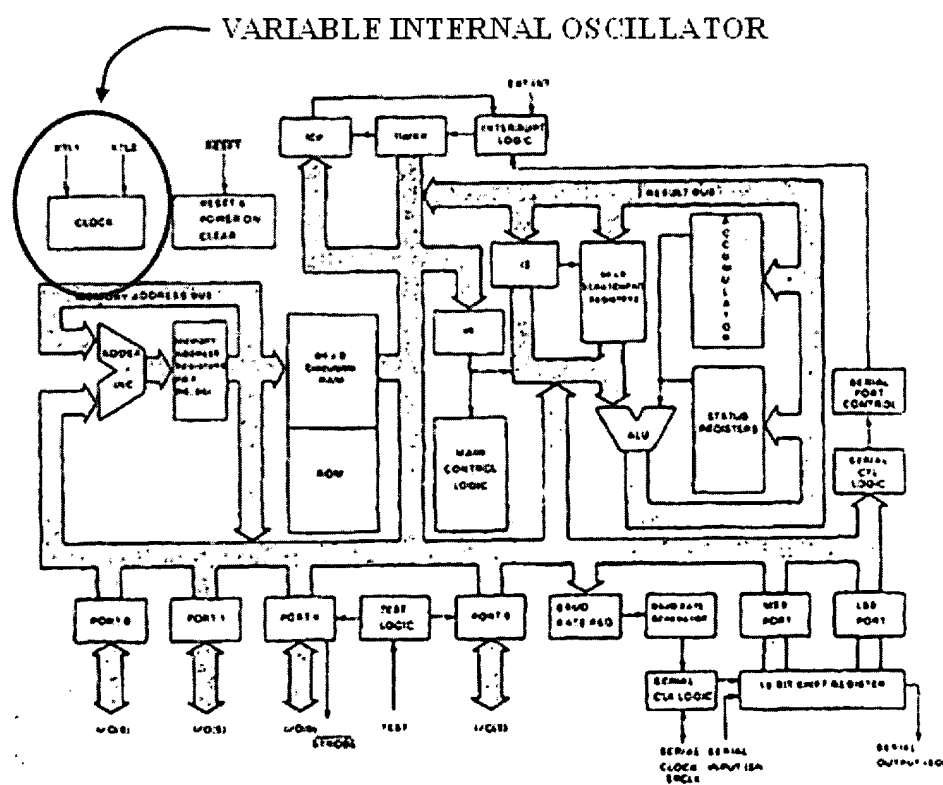

Teaching of the Mostek Reference

1.7 – 4 MHz when the chips are set to Internal Mode by grounding XTL₁ and XTL₂. (Appendix J, Fig. 3; Pages 2024 and 2026).

INTERNAL MODE

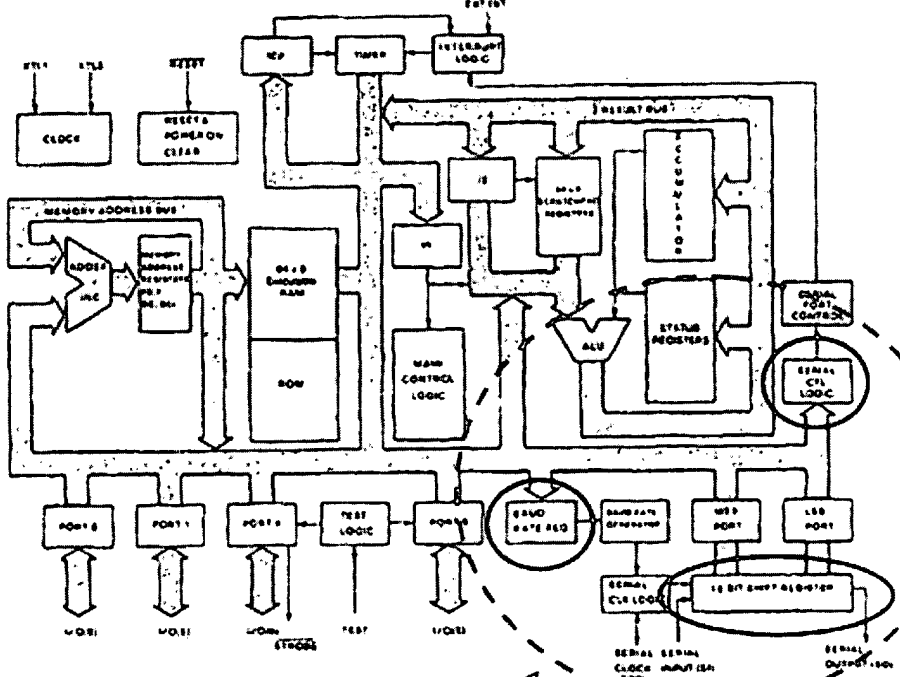

(Appendix J, Fig. 4 at page 2029).

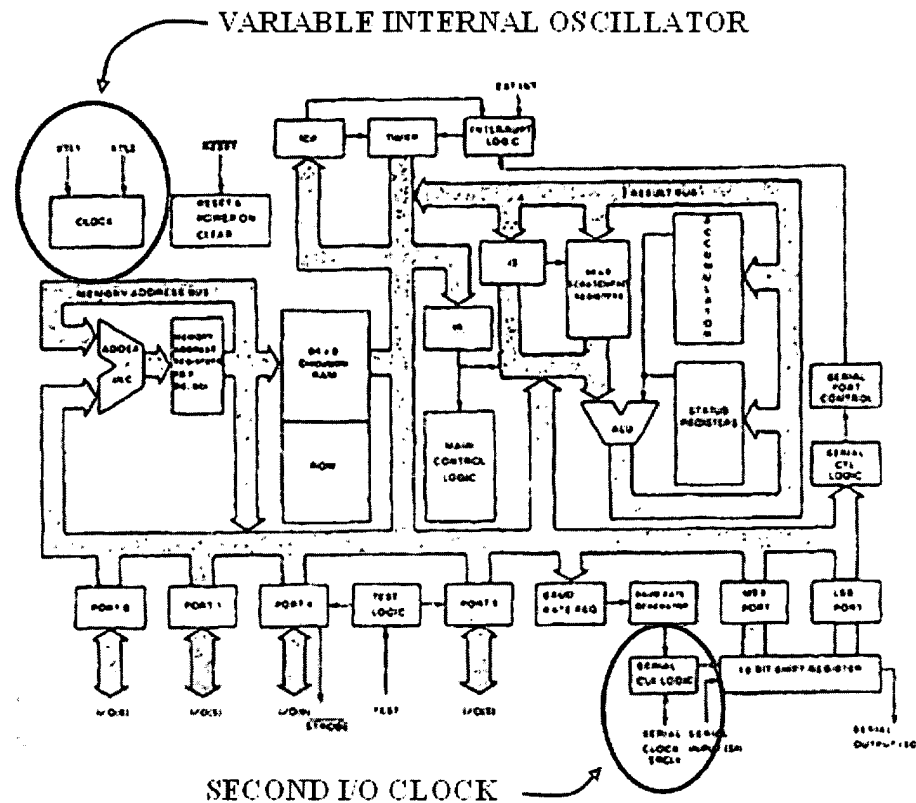

The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today's

Claim Limitation	Teaching of the Mostek Reference
	<p>processors, would also be true with regard to the Mostek 3870 family of processors. Accordingly, if the office accepts this premise, one skilled in the art would have understood Mostek to disclose a ring oscillator for clocking the central processing unit.</p> <p>Alternatively, the use of a ring oscillator as Mostek's variable internal oscillator is obvious in view of United States Patent No. 4,766,567 to Kato. Kato describes a ring oscillator that can be used to supply clock signals for the CPU described in Mostek. This is because Kato similarly describes a "one-chip semiconductor device" (<i>Appendix H, col. 1, lines 6-9</i>) that utilizes a ring oscillator because the device "<u>need not have a very accurate frequency.</u>" (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). The ring oscillator's "output frequency lowers in proportion to the speed of the data processing circuit which is lowered due to the drop of power supply voltage." (<i>Appendix H, col. 11, lines 1-5</i>). One skilled in the art would have seen an apparent reason to implement Kato's ring oscillator as the variable speed oscillator of Mostek, namely because the family of chips described by the Mostek data book also operate from their internal oscillators when "timing is not critical" and a ring oscillator is an obvious selection for an internal oscillator. (<i>Appendix J, page 2019</i>). One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Mostek's variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
<p>said central processing unit and said ring oscillator variable speed system clock each including a plurality of electronic devices correspondingly constructed of the same process technology with corresponding manufacturing variations,</p>	<p>One skilled in the art would understand the on-chip oscillator circuit and the main control logic to include a plurality of electronic devices.</p> <p>With respect to the limitation of the CPU and ring oscillator being constructed of the same process technology, Mostek teaches a microprocessor system fabricated on a single chip, which would necessarily be constructed by a single process technology. Mostek describes the internal oscillator as an "on-chip oscillator circuit" indicating that the oscillator is fabricated on the same chip as the CPU and that the oscillator and CPU would therefore be constructed by the same process technology. (<i>Appendix F, page III-114</i>)</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of "the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the</p>

Claim Limitation	Teaching of the Mostek Reference
	<p>ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. (“Ledzius”). Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Mostek, namely to produce Mostek’s processor with minimal cost and defects.</p>
<p>a processing frequency capability of said central processing unit and a speed of said ring oscillator variable speed system clock varying together due to said manufacturing variations and due to at least operating voltage and temperature of said single integrated circuit;</p>	<p>Mostek’s microcomputer varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%, as one skilled in the art would understand by referencing the IC Master data book that describes the entire 3870 family. (<i>Appendix J, pages 2025-2026</i>).</p> <p>In any case, the Patent Owner has stated in correspondence to various third parties that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>).</p> <p>Additionally and as describe previously, one skilled in the art would see an apparent reason to implement the ring oscillator of Kato as the variable oscillator of Mostek. One skilled in the art would realize the benefits of implementing Kato’s ring oscillator as Mostek’s variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results</p>

Claim Limitation	Teaching of the Mostek Reference
	<p>in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Mostek, namely to produce the processor of Mostek with minimal cost and defects.</p>
<p>an on-chip input/output interface connected to exchange coupling control signals, addresses and data with said central processing unit;</p>	<p>Mostek teaches a “Serial Input/Output Port [that] consists of a serial Shift Register, baud rate generator, and control logic.” (<i>Appendix F, page III-105</i>).</p>  <p>The diagram illustrates the internal architecture of the Mostek processor. Key components include: <ul style="list-style-type: none"> External Inputs: RESET, POWER ON CLEAR, and TEST. Internal Control: CPU, TIMER, INTERRUPT LOGIC, and MAIN CONTROL LOGIC. Memory: MEMORY ADDRESS BUS, ADDRESS DECODE, MEMORY, and ROM. Arithmetic/Logic: ALU, STATUS REGISTER, and REGISTER FILE. Serial I/O Port (highlighted with a dashed circle): Includes a SERIAL RATE REG, BAUD RATE GENERATOR, SERIAL CLK LOGIC, and a 16 BIT SHIFT REGISTER. It is connected to SERIAL INPUT and SERIAL OUTPUT lines. Other Ports: PORT 0, PORT 1, PORT 2, and TEST LOGIC. </p> <p>SERIAL INPUT/OUTPUT PORT</p> <p>(<i>Appendix F, Figure 1 at page III-103</i>).</p>
<p>and a second clock independent of said ring oscillator variable speed system clock connected to said input/output interface.</p>	<p>Mostek teaches that “[d]ata is shifted into or out of the shift register at a rate determined by [an] external clock.” (<i>Appendix F, page III-105</i>). The serial I/O port clocking signal “is derived from the SRCLK pulse. The SRCLK pulse . . . may be programmed as an input.” (<i>Appendix F, page III-105</i>). Mostek’s main control unit is clocked by the separate, independent “on-chip oscillator circuit.” (<i>Appendix F, pages III-114 to III-115; Figure 1 at page III-103</i>).</p>

Claim Limitation	Teaching of the Mostek Reference
	<p style="text-align: center;">Teaching of the Mostek Reference</p>  <p style="text-align: center;">(Appendix F, Figure 1 at page III-103).</p>
<p>Claim 2</p> <p>2. The microprocessor system of claim 1 in which said second clock is a fixed frequency clock.</p>	<p>Mostek teaches the use of a fixed frequency 3.6864MHz crystal with the second I/O clock. (Appendix F, page III-109). Additionally, Mostek notes that “<u>any</u> TTL compatible square wave input can be used to generate the clock for the serial port.” (Appendix F, page III-110).</p>
<p>Claim 3</p> <p>3. In a microprocessor integrated circuit,</p>	<p>This feature is taught by Mostek, 3870 Microcomputer Data Book (Feb. 1981) (“Mostek”). Claim Limitation	Teaching of the Mostek Reference
microprocessor are located within the same integrated circuit, vary together with operating characteristics of electronic devices included within the microprocessor;	<p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. (“Ledzius”). Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Mostek, namely to produce Mostek’s processor with minimal cost and defects.</p>
using the ring oscillator system clock for clocking the microprocessor,	As explained above, Mostek teaches an “on-chip oscillator circuit which provides an internal clock” for clocking the microprocessor
said microprocessor operating at a variable processing frequency dependent upon a variable speed of said ring oscillator system clock;	<p>Mostek’s microcomputer varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%, as one skilled in the art would understand by referencing the IC Master data book that describes the entire 3870 family. (<i>Appendix J, pages 2025-2026</i>).</p> <p>In any case, the Patent Owner has stated in correspondence to various third parties that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B,</i></p>

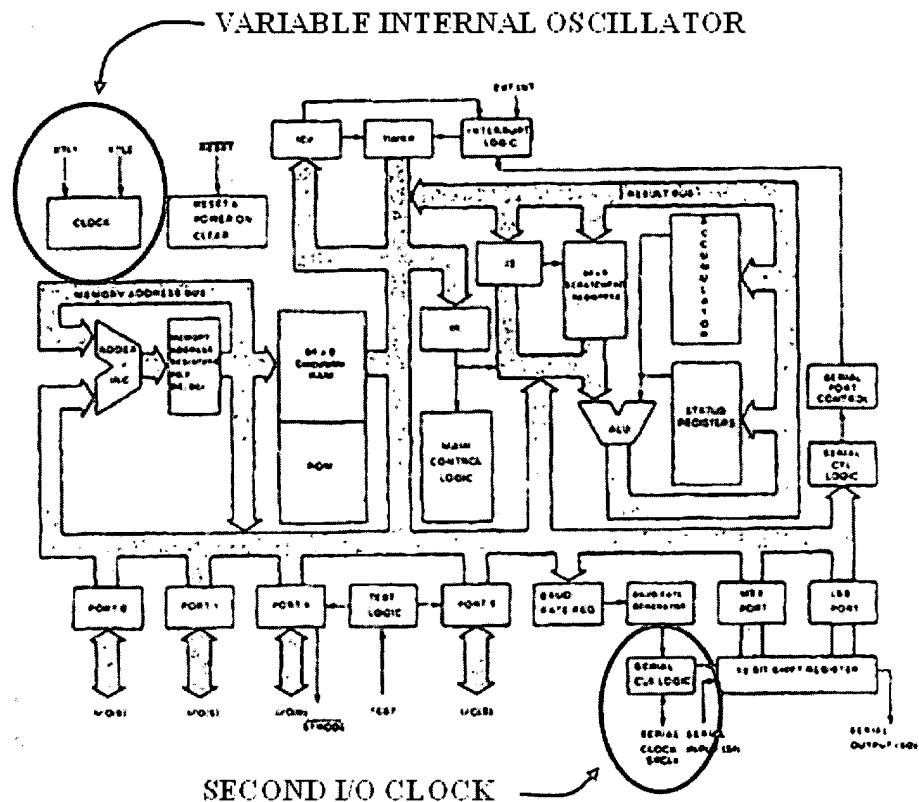

<p>Claim Limitation</p>	<p align="center">Teaching of the Mostek Reference</p> <p><i>April 15, 1996 Applicant Arguments, original page 6.)</i></p> <p>Additionally and as describe previously, one skilled in the art would see an apparent reason to implement the ring oscillator of Kato as the variable oscillator of Mostek. One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Mostek's variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7).</i></p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the "same batch and section of semiconductor wafer" results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21).</i> One skilled in the art would have found an apparent reason to combine Ledzius with Mostek, namely to produce the processor of Mostek with minimal cost and defects.</p>
<p>providing an on chip input/output interface for the microprocessor integrated circuit; and</p>	<p>Mostek teaches a "Serial Input/Output Port [that] consists of a serial Shift Register, baud rate generator, and control logic." (<i>Appendix F, page III-105).</i></p> <div style="text-align: center;"> <p>SERIAL INPUT/OUTPUT PORT</p> </div> <p align="right">(Appendix F, Figure 1 at page III-103).</p>
<p>clocking the</p>	<p>Mostek teaches that "[d]ata is shifted into or out of the shift register at a rate</p>

Claim Limitation

input/output interface with a second clock independent of the ring oscillator system clock.

Teaching of the Mostek Reference

determined by [an] external clock.” (*Appendix F, page III-105*). The serial I/O port clocking signal “is derived from the SRCLK pulse. The SRCLK pulse . . . may be programmed as an input.” (*Appendix F, page III-105*). Mostek’s main control unit is clocked by the separate, independent “on-chip oscillator circuit.” (*Appendix F, pages III-114 to III-115; Figure 1 at page III-103*).

(*Appendix F, Figure 1 at page III-103*).

Claim 4

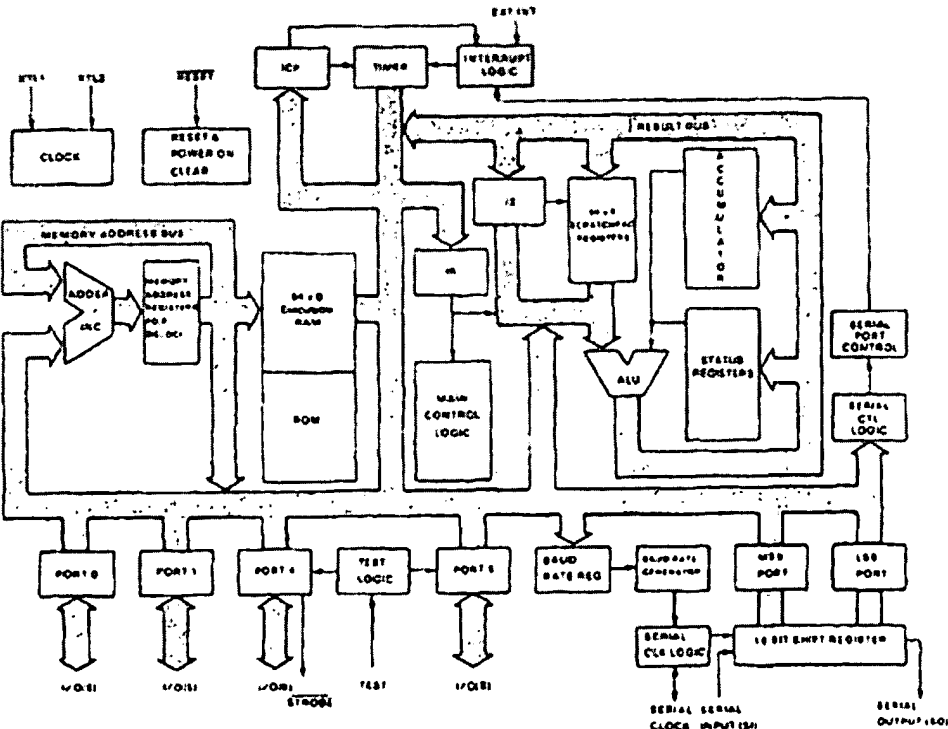

4. The method of claim 3 in which the second clock is a fixed frequency clock.

Mostek teaches the use of a fixed frequency 3.6864MHz crystal with the second I/O clock. (*Appendix F, page III-109*). Additionally, Mostek notes that “any TTL compatible square wave input can be used to generate the clock for the serial port.” (*Appendix F, page III-110*).

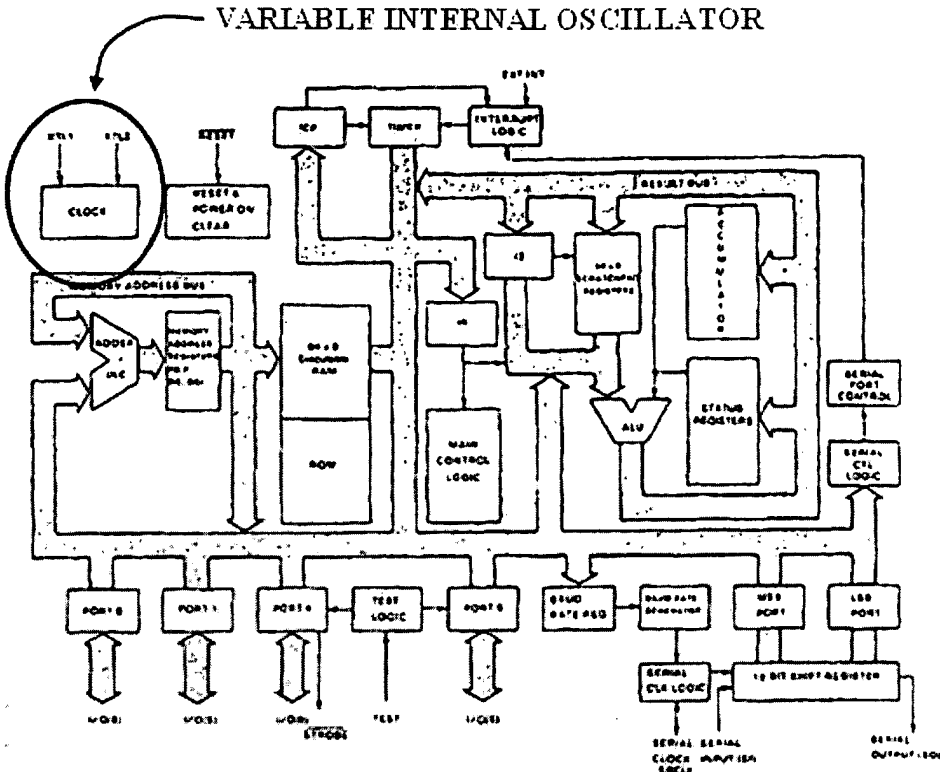

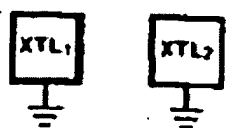

Claim 5

5. The method of claim 3 further including the step of: transferring information to and from said

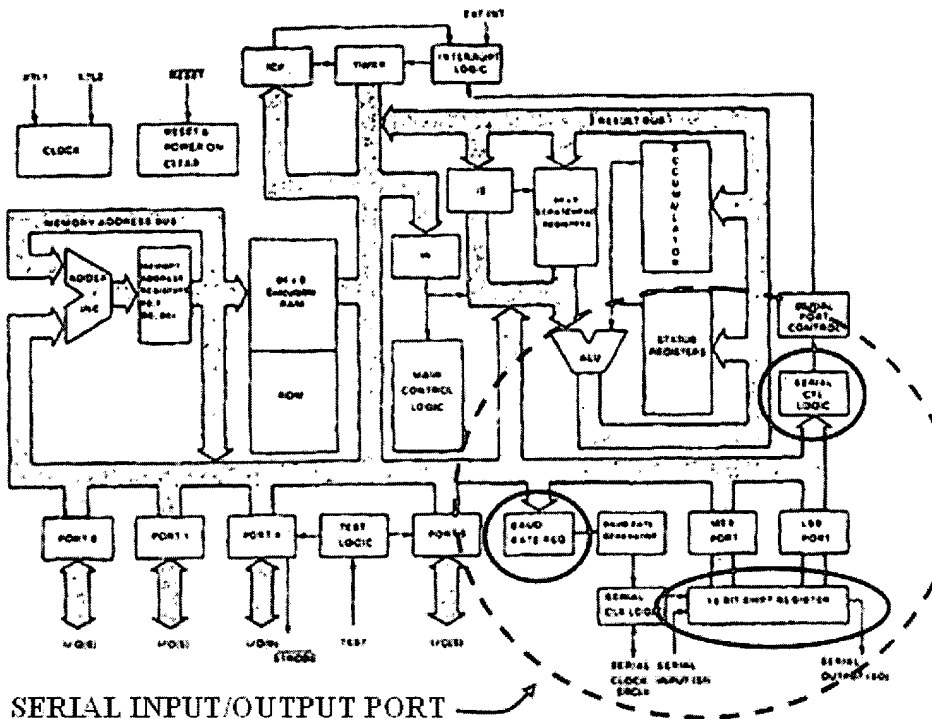

Mostek describes a machine “short cycle, during which time an op code fetch is performed.” (*Appendix F, pages III-113*). One skilled in the art would understand that Mostek’s main control logic performs the op code fetch. (*Appendix J, page 2019*). The short cycle is based on the time base frequency, which is established by the on-chip oscillator circuit. (*Appendix F, pages III-112 to III-114*).

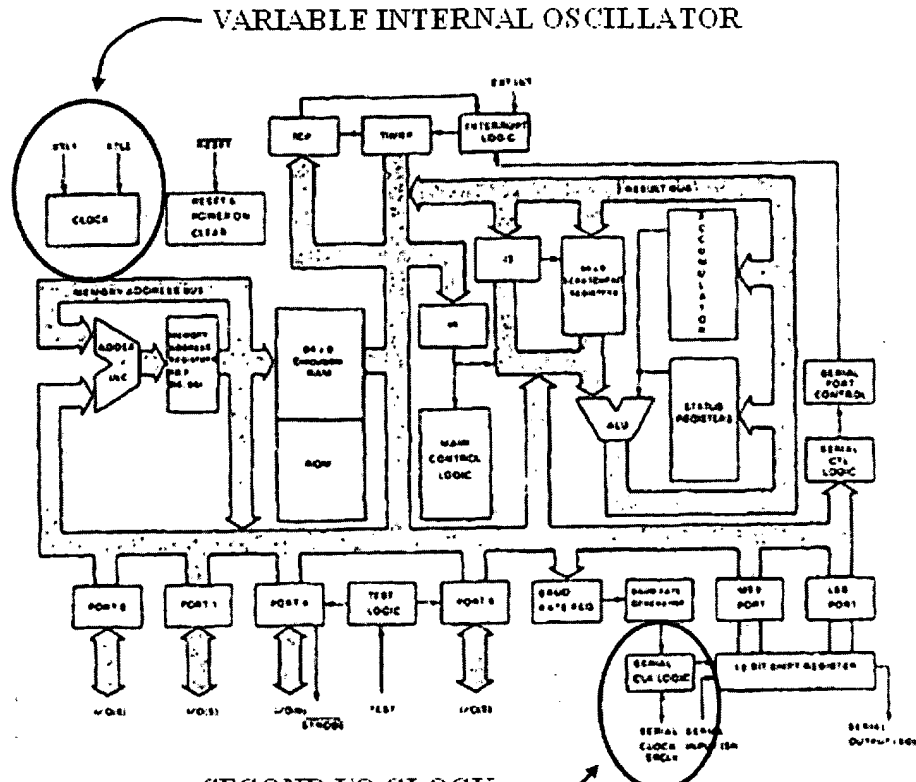

Claim Limitation	Teaching of the Mostek Reference
microprocessor in synchrony with said ring oscillator system clock.	
Claim 6	
<p>6. A microprocessor system comprising:</p> <p>a central processing unit disposed upon an integrated circuit substrate,</p>	<p>This feature is taught by Mostek, 3870 Microcomputer Data Book (Feb. 1981) ("Mostek"). The Mostek reference discloses a "<i>single chip microcomputer</i>" with features including a main control logic, executable RAM, ROM, and a serial input/output port. (<i>Appendix F, pages III-102 and III-103</i>).</p> <p>Mostek teaches a central processing unit, as indicated by discussion of the microcomputer's "CPU over head," "CPU instructions," "CPU Registers," and "processing . . . that occupies the CPU." (<i>Appendix F, pages III-102, III-104, and VI-8</i>). One skilled in the art would understand Mostek's Main Control Logic to disclose the recited CPU as the Main Control Logic "provides the necessary control gating signals to all circuit elements," as noted by another data book describing the 3870 family of chips (<i>Appendix J, page 2019</i>). The MK3873 described by Mostek includes architecture that is "identical to that of the rest of the devices in the 3870 family with the exception of the serial port logic." (<i>Appendix F, page III-102</i>).</p>  <p>(<i>Appendix F, Figure 1 at page III-103</i>).</p>

Claim Limitation	Teaching of the Mostek Reference
<p>said central processing unit operating at a processing frequency and being constructed of a first plurality of electronic devices;</p>	<p>Mostek teaches an “on-chip oscillator circuit which provides an internal clock” for clocking the CPU. The internal oscillators of the 3870 family chips are disclosed to operate within a varying frequency range of 1.7 – 4 MHz when the chips are set to Internal Mode by grounding XTL₁ and XTL₂. (<i>Appendix J, Fig. 3; Pages 2024 and 2026</i>).</p> <div data-bbox="836 514 1112 735" data-label="Diagram"> <p style="text-align: center;">INTERNAL MODE</p> <p style="text-align: center;">$f = 1.7 - 4 \text{ MHz}$</p> </div> <p style="text-align: center;">(<i>Appendix J, Fig. 4 at page 2029</i>).</p> <p>One skilled in the art would understand the CPU to include a plurality of electronic devices.</p>
<p>an entire oscillator disposed upon said integrated circuit substrate and connected to said central processing unit,</p>	<p>Mostek teaches an “on-chip oscillator circuit which provides an internal clock.” (<i>Appendix F, pages III-114 to III-115</i>). Additionally, Mostek states that “the architecture of the MK3873 is identical to that of the rest of the devices in the 3870 family with the exception of the serial port logic.” (<i>Appendix F, page III-102</i>). One skilled in the art would know that the 3870 family of chips contain variable internal oscillators as described by the IC Master databook (IC Master 1980 (United Technical Publications) (1980)). For example, the IC Master databook states that “<u>If timing is not critical</u>, the F3870 will operate from its internal oscillator with no external components” (<i>Appendix J, page 2019</i>) (<i>emphasis added</i>). The internal oscillators of the 3870 family chips are disclosed to vary in frequency from 1.7 – 4 MHz when the chips are set to Internal Mode by grounding XTL₁ and XTL₂. (<i>Appendix J, Fig. 3; Pages 2024 and 2026</i>).</p> <div data-bbox="820 1543 1096 1774" data-label="Diagram"> <p style="text-align: center;">INTERNAL MODE</p> <p style="text-align: center;">$f = 1.7 - 4 \text{ MHz}$</p> </div> <p style="text-align: center;">(<i>Appendix J, Fig. 4 at page 2029</i>).</p>

Claim Limitation	Teaching of the Mostek Reference
	<p style="text-align: center;">VARIABLE INTERNAL OSCILLATOR</p>  <p style="text-align: center;">(Appendix F, Figure 1 at page III-103).</p>
<p>said oscillator clocking said central processing unit at a clock rate and being constructed of a second plurality of electronic devices,</p>	<p>Mostek teaches an “on-chip oscillator circuit which provides an internal clock” for clocking the CPU. The internal oscillators of the 3870 family chips are disclosed to operate within a varying frequency range of 1.7 – 4 MHz when the chips are set to Internal Mode by grounding XTL₁ and XTL₂. (Appendix J, Fig. 3; Pages 2024 and 2026).</p> <p style="text-align: center;">INTERNAL MODE</p>  <p style="text-align: center;">f = 1.7 – 4 MHz.</p> <p style="text-align: center;">(Appendix J, Fig. 4 at page 2029).</p> <p>One skilled in the art would understand the oscillator to include a plurality of electronic devices.</p>

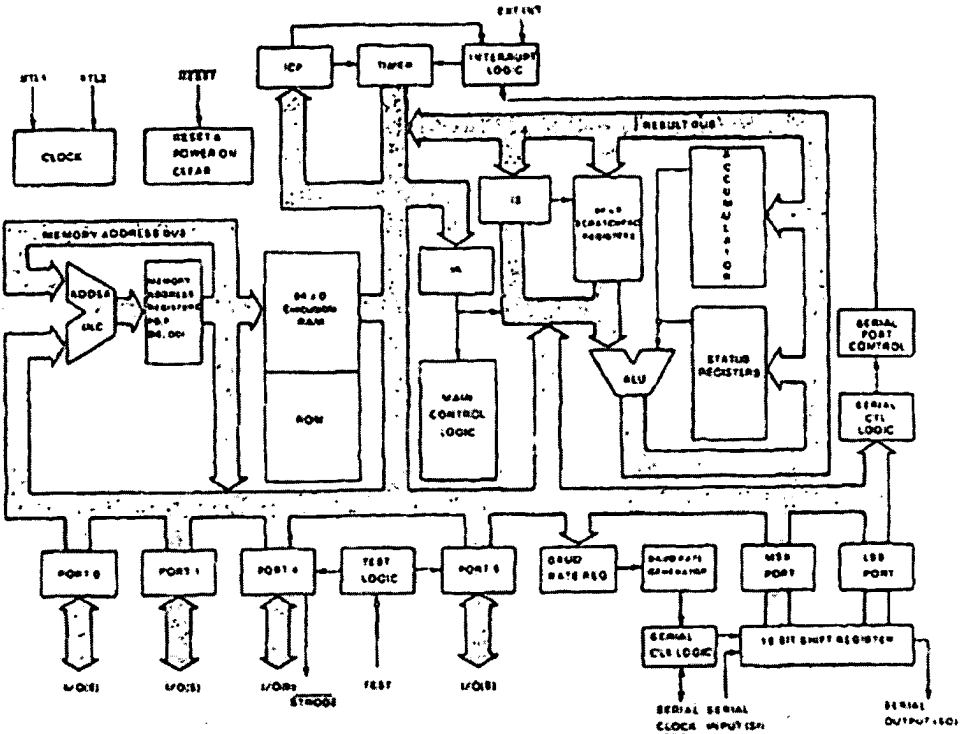

Claim Limitation	Teaching of the Mostek Reference
	<p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
<p>thus varying the processing frequency of said first plurality of electronic devices and the clock rate of said second plurality of electronic devices in the same way as a function of parameter variation in one or more fabrication or operational parameters associated with said integrated circuit substrate, thereby enabling said processing frequency to track said clock rate in response to said parameter variation;</p>	<p>Mostek teaches a microprocessor system fabricated on a single chip, which would necessarily be constructed by a single process technology. Mostek describes the internal oscillator as an “on-chip oscillator circuit” indicating that the oscillator is fabricated on the same chip as the CPU and that the oscillator and CPU would therefore be constructed by the same process technology. (<i>Appendix F, page III-114</i>)</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. (“Ledzius”). Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Mostek, namely to produce Mostek’s processor with minimal cost and defects.</p>
<p>an on-chip input/output interface, connected between said said [sic] central processing unit and an external memory bus, for facilitating exchanging coupling control signals, addresses and data with said central processing unit; and</p>	<p>Mostek teaches a “Serial Input/Output Port [that] consists of a serial Shift Register, baud rate generator, and control logic.” (<i>Appendix F, page III-105</i>).</p> <p>Mostek teaches that the serial port is “very flexible so that it could be used for other purposes such as an interface to . . . serial memory devices.” (<i>Appendix F, page III-102, col. 1</i>).</p>

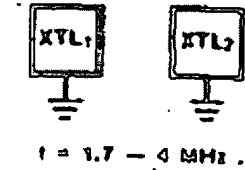

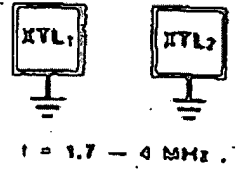

Claim Limitation	Teaching of the Mostek Reference
	 <p style="text-align: center;">SERIAL INPUT/OUTPUT PORT</p> <p style="text-align: center;">(Appendix F, Figure 1 at page III-103).</p>
<p>an external clock, independent of said oscillator, connected to said input/output interface wherein said external clock is operative at a frequency independent of a clock frequency of said oscillator.</p>	<p>Mostek teaches that “[d]ata is shifted into or out of the shift register at a rate determined by [an] external clock.” (<i>Appendix F, page III-105</i>). The serial I/O port clocking signal “is derived from the SRCLK pulse. The SRCLK pulse . . . may be programmed as an input.” (<i>Appendix F, page III-105</i>). Mostek’s main control unit is clocked by the separate, independent “on-chip oscillator circuit.” (<i>Appendix F, pages III-114 to III-115; Figure 1 at page III-103</i>).</p>

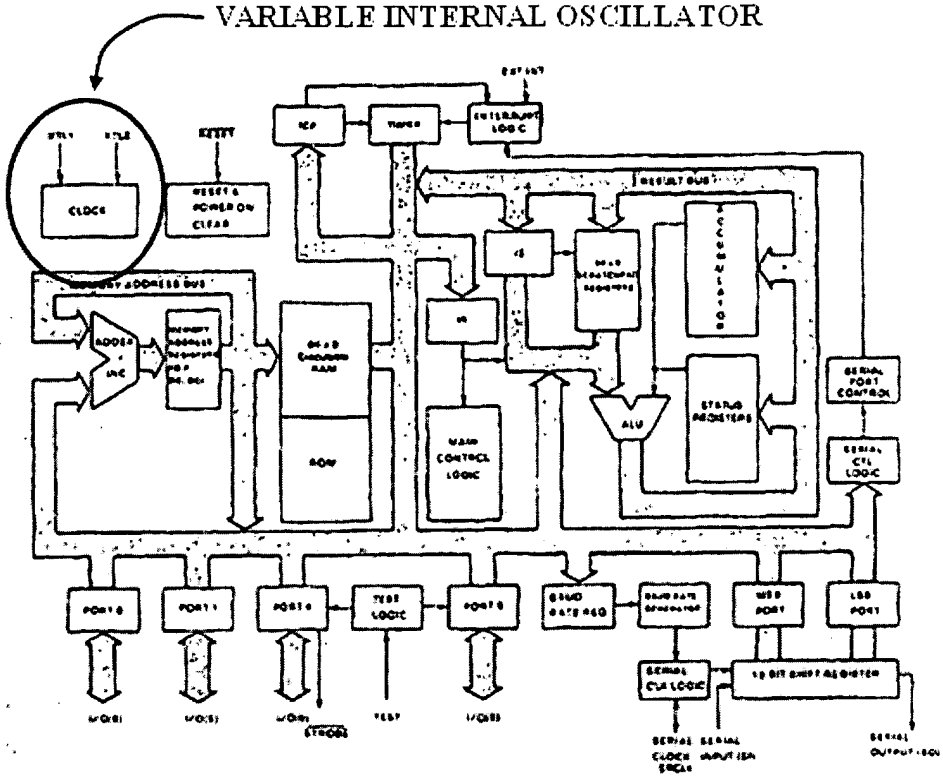

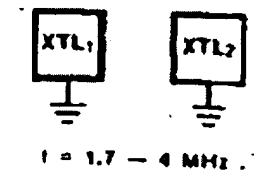

Claim Limitation	Teaching of the Mostek Reference
	<p style="text-align: center;">VARIABLE INTERNAL OSCILLATOR</p>  <p style="text-align: center;">SECOND I/O CLOCK</p> <p style="text-align: center;">(Appendix F, Figure 1 at page III-103).</p>
<p>Claim 7</p> <p>7. The microprocessor system of claim 6 wherein said one or more operational parameters include operating temperature of said substrate or operating voltage of said substrate.</p>	<p>Mostek's microcomputer varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%, as one skilled in the art would understand by referencing the IC Master data book that describes the entire 3870 family. (Appendix J, pages 2025-2026).</p> <p>In any case, the Patent Owner has stated in correspondence to various third parties that because of "the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature." (Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6).</p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the "same batch and section of semiconductor wafer" results in frequency variations due to process and temperature variations throughout the circuit. (Appendix I, col. 4, lines 3-21). One skilled in the</p>

Claim Limitation	Teaching of the Mostek Reference
	art would have found an apparent reason to combine Ledzius with Mostek, namely to produce the processor of Mostek with minimal cost and defects.
Claim 8	
<p>8. The microprocessor system of claim 6 wherein said external clock comprises a fixed-frequency clock which operates synchronously relative to said oscillator.</p>	<p>Mostek teaches the use of a fixed frequency 3.6864MHz crystal with the second I/O clock. (<i>Appendix F, page III-109</i>).</p> <p>The limitation of the I/O clock operating synchronously relative to the oscillator is taught by Kato. Kato teaches a microprocessor system having two clock. The first clock generator clocks the CPU and the second clock generator is connected to the I/O port. (<i>Appendix H, col. 4, lines 37-42 and FIG. 4</i>)</p> <p>Kato teaches that the first and second clock generators operate synchronously: “second clock generator 15 produces two clock signals ϕ_a and ϕ_b... Signals ϕ_a and ϕ_b are produced in synchronism with the signal from first clock generator 14.” (<i>Appendix H, col. 4, lines 56-60</i>) As explained above, one skilled in the art would have found an apparent reason to combine the teachings of Kato and Mostek, namely to provide Mostek with a ring oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
Claim 9	
<p>9. The microprocessor system of claim 6 wherein said oscillator comprises a ring oscillator.</p>	<p>The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today’s processors, would also be true with regard to the Mostek 3870 family of processors. Accordingly, if the office accepts this premise, one skilled in the art would have understood Mostek to disclose a ring oscillator for clocking the central processing unit.</p> <p>Alternatively, the use of a ring oscillator as Mostek’s variable internal oscillator is obvious in view of United States Patent No. 4,766,567 to Kato. Kato describes a ring oscillator that can be used to supply clock signals for the CPU described in Mostek. This is because Kato similarly describes a “one-chip semiconductor device” (<i>Appendix H, col. 1, lines 6-9</i>) that utilizes a ring oscillator because the device “<u>need not have a very accurate frequency.</u>” (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). The ring oscillator’s “output frequency lowers in proportion to the speed of the data</p>

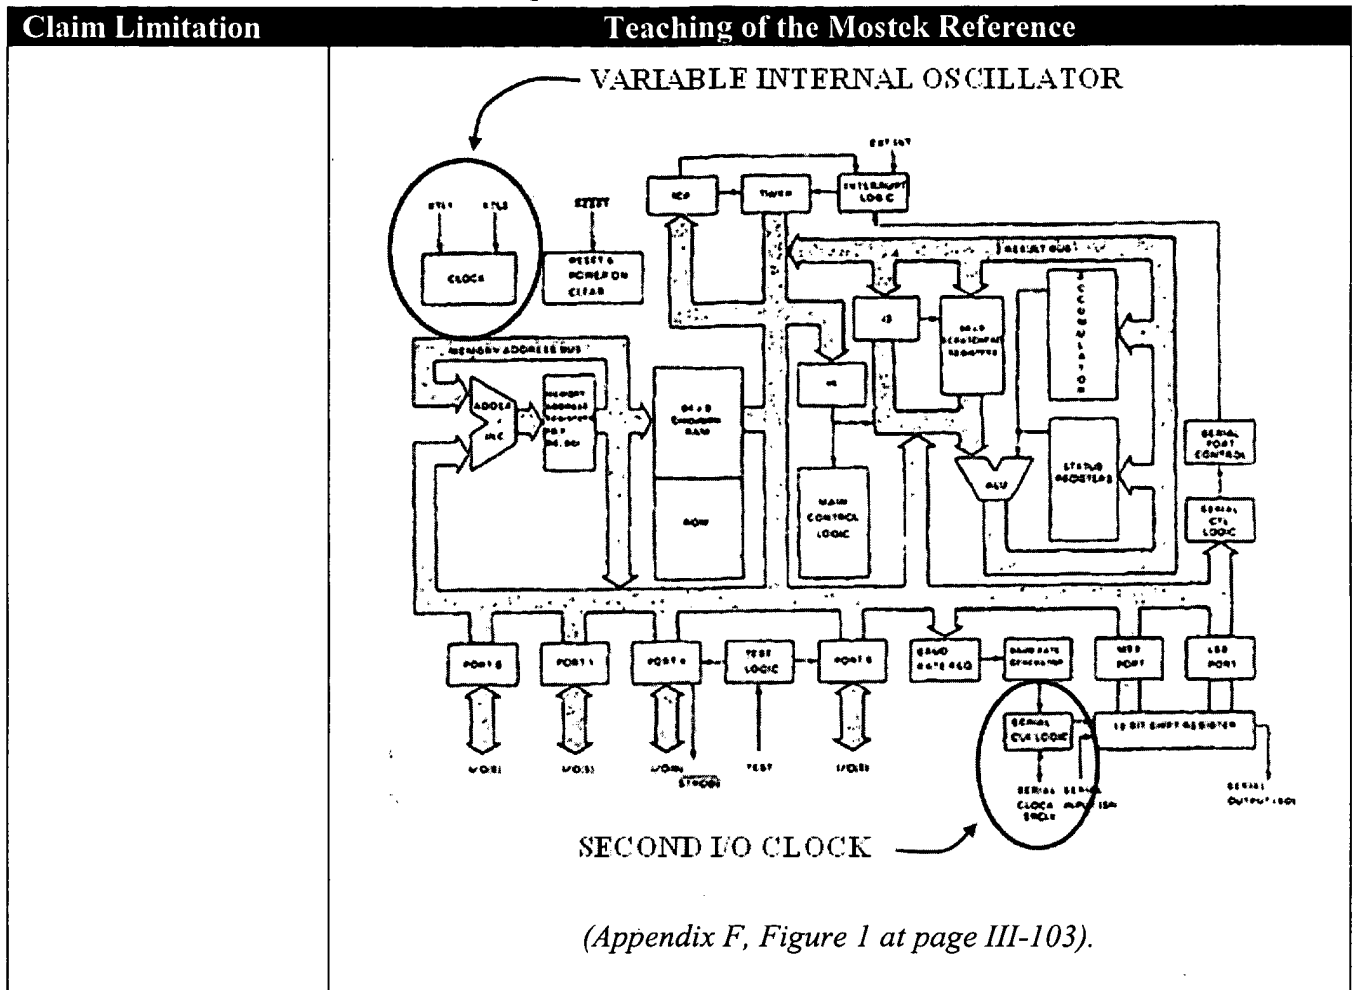

Claim Limitation	Teaching of the Mostek Reference
	<p>processing circuit which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 1-5</i>). One skilled in the art would have seen an apparent reason to implement Kato’s ring oscillator as the variable speed oscillator of Mostek, namely because the family of chips described by the Mostek data book also operate from their internal oscillators when “timing is not critical” and a ring oscillator is an obvious selection for an internal oscillator. (<i>Appendix J, page 2019</i>). One skilled in the art would realize the benefits of implementing Kato’s ring oscillator as Mostek’s variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
Claim 10	
<p>10. In a microprocessor system including a central processing unit,</p>	<p>This feature is taught by Mostek, 3870 Microcomputer Data Book (Feb. 1981) (“Mostek”). The Mostek reference discloses a “<i>single chip microcomputer</i>” with features including a main control logic, executable RAM, ROM, and a serial input/output port. (<i>Appendix F, pages III-102 and III-103</i>).</p> <p>Mostek teaches a central processing unit, as indicated by discussion of the microcomputer’s “CPU over head,” “CPU instructions,” “CPU Registers,” and “processing . . . that occupies the CPU.” (<i>Appendix F, pages III-102, III-104, and VI-8</i>). One skilled in the art would understand Mostek’s Main Control Logic to disclose the recited CPU as the Main Control Logic “provides the necessary control gating signals to all circuit elements,” as noted by another data book describing the 3870 family of chips (<i>Appendix J, page 2019</i>). The MK3873 described by Mostek includes architecture that is “identical to that of the rest of the devices in the 3870 family with the exception of the serial port logic.” (<i>Appendix F, page III-102</i>).</p>

Claim Limitation	Teaching of the Mostek Reference
	 <p>(Appendix F, Figure 1 at page III-103).</p>
<p>a method for clocking said central processing unit comprising the steps of:</p>	<p>Mostek teaches an “on-chip oscillator circuit which provides an internal clock” for clocking the CPU.</p>
<p>providing said central processing unit upon an integrated circuit substrate,</p>	<p>The Mostek reference discloses a “<i>single chip microcomputer</i>” which includes a CPU as described above.</p>
<p>said central processing unit being constructed of a first plurality of transistors and being operative at a processing frequency;</p>	<p>One skilled in the art would understand the CPU to include a plurality of transistors.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of transistors.</p> <p>Mostek teaches an “on-chip oscillator circuit which provides an internal clock” for clocking the CPU. The internal oscillators of the 3870 family chips are disclosed to operate within a varying frequency range of 1.7 – 4 MHz when the chips are set to Internal Mode by grounding XTL₁ and XTL₂. (Appendix J, Fig. 3; Pages 2024 and 2026).</p>

Claim Limitation	Teaching of the Mostek Reference
	<p style="text-align: center;">INTERNAL MODE</p>  <p style="text-align: center;">$f = 1.7 - 4 \text{ MHz}$</p> <p style="text-align: center;">(Appendix J, Fig. 4 at page 2029).</p>
<p>providing an entire variable speed clock disposed upon said integrated circuit substrate,</p>	<p>Mostek teaches an “on-chip oscillator circuit which provides an internal clock.” (Appendix F, pages III-114 to III-115). Additionally, Mostek states that “the architecture of the MK3873 is identical to that of the rest of the devices in the 3870 family with the exception of the serial port logic.” (Appendix F, page III-102). One skilled in the art would know that the 3870 family of chips contain variable internal oscillators as described by the IC Master databook (IC Master 1980 (United Technical Publications) (1980)). For example, the IC Master databook states that “<u>If timing is not critical</u>, the F3870 will operate from its internal oscillator with no external components” (Appendix J, page 2019) (<i>emphasis added</i>). The internal oscillators of the 3870 family chips are disclosed to vary in frequency from 1.7 – 4 MHz when the chips are set to Internal Mode by grounding XTL₁ and XTL₂. (Appendix J, Fig. 3; Pages 2024 and 2026).</p> <p style="text-align: center;">INTERNAL MODE</p>  <p style="text-align: center;">$f = 1.7 - 4 \text{ MHz}$</p> <p style="text-align: center;">(Appendix J, Fig. 4 at page 2029).</p>

Claim Limitation	Teaching of the Mostek Reference
	<p style="text-align: center;">VARIABLE INTERNAL OSCILLATOR</p>  <p style="text-align: center;">(Appendix F, Figure 1 at page III-103).</p>
<p>said variable speed clock being constructed of a second plurality of transistors;</p>	<p>One skilled in the art would understand the oscillator to include a plurality of transistors.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of transistors.</p>
<p>clocking said central processing unit at a clock rate using said variable speed clock with said central processing unit being clocked by said variable speed clock</p>	<p>Mostek teaches an “on-chip oscillator circuit which provides an internal clock” for clocking the CPU. The internal oscillators of the 3870 family chips are disclosed to operate within a varying frequency range of 1.7 – 4 MHz when the chips are set to Internal Mode by grounding XTL₁ and XTL₂. (Appendix J, Fig. 3; Pages 2024 and 2026).</p> <p style="text-align: center;">INTERNAL MODE</p>  <p style="text-align: center;">f = 1.7 - 4 MHz</p>

Claim Limitation	Teaching of the Mostek Reference
	<p align="center"><i>(Appendix J, Fig. 4 at page 2029).</i></p>
<p>at a variable frequency dependent upon variation in one or more fabrication or operational parameters associated with said integrated circuit substrate, said processing frequency and said clock rate varying in the same way relative to said variation in said one or more fabrication or operational parameters associated with said integrated circuit substrate;</p>	<p>The internal oscillators of the 3870 family chips are disclosed to operate within a varying frequency range of 1.7 – 4 MHz as described above.</p> <p>Mostek teaches a microprocessor system fabricated on a single chip, which would necessarily be constructed by a single process technology. Mostek describes the internal oscillator as an “on-chip oscillator circuit” indicating that the oscillator is fabricated on the same chip as the CPU and that the oscillator and CPU would therefore be constructed by the same process technology. <i>(Appendix F, page III-114)</i></p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations.” <i>(Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6).</i></p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. (“Ledzius”). Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. <i>(Appendix I, col. 4, lines 11-12).</i> One skilled in the art would have found an apparent reason to combine Ledzius with Mostek, namely to produce Mostek’s processor with minimal cost and defects.</p>
<p>connecting an on chip input/output interface between said central processing unit and an external memory bus, and exchanging coupling control signals, addresses and data between said input/output interface</p>	<p>Mostek teaches a “Serial Input/Output Port [that] consists of a serial Shift Register, baud rate generator, and control logic.” <i>(Appendix F, page III-105).</i></p> <p>Mostek teaches that the serial port is “very flexible so that it could be used for other purposes such as an interface to . . . serial memory devices.” <i>(Appendix F, page III-102, col. 1).</i></p>

From the foregoing chart, it can be seen that claims 1-10 are anticipated and rendered obvious by Mostek. Thus, claims 1-10 are unpatentable as being anticipated under 35 U.S.C. § 102(b) and/or obvious under U.S.C. § 103 in view of the Mostek reference.

E. The Mostek Reference Anticipates or Renders Obvious the Newly Introduced Claims of the '336 Patent

The Mostek reference anticipates or renders obvious new claims added during the patent's ongoing merged reexamination. The Patent Owner added claims 11-20 which parallel respective original claims 1-10 except that they further include a limitation to "more clearly set forth the meaning of 'independent.'" (*Appendix C, Amendment, Sept. 8, 2008, original page 11*). The additional limitations append the parallel independent claims and recite: "thereby enabling decoupling a speed of said central processing unit from a speed of said input/output interface." (*Id.*).

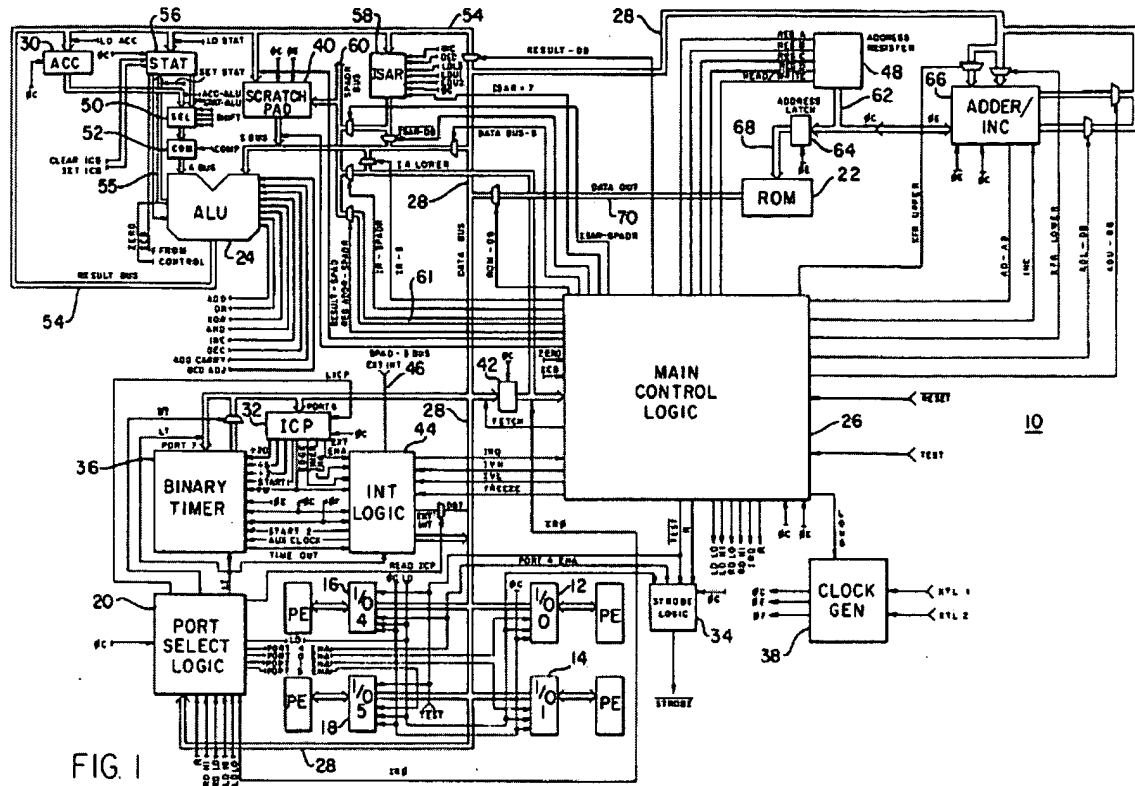

The serial I/O port taught by Mostek is optionally clocked by an “external clock” that is distinct and decoupled in speed from the internal oscillator that provides the clock signal to the rest of the circuit. (*Appendix F, pages III-102 and III-105*). Accordingly, the input/output port generates an “end-of-word interrupt” in order to notify the CPU that a word has been received. (*Appendix F, pages III-105 and III-109*).

IX. THE DOZIER REFERENCE ANTICIPATES OR RENDERS OBVIOUS CLAIMS 1-10 OF THE ‘336 PATENT

The prior art references provided in this request raise substantial new questions of patentability as to claims 1-10 of the ‘336 patent. Specifically, all claims are anticipated by the Dozier reference and are additionally rendered obvious over Dozier in light of the Mostek reference, the Kato reference, and the Ledzius reference.

A. Summary of the Teachings of the Dozier Reference

The Dozier reference teaches a microprocessor that is implemented on a single semiconductor chip, contains a main control logic that is clocked by an internal oscillator, and has input/output ports. Specifically, the reference discloses a “microprogrammed computer 10 which may be implemented by MOS/LSI techniques and which may be fabricated on a single semiconductor chip.” (*Appendix E, col. 2, lines 60-63*). The reference discloses a preferred embodiment, in which “[t]he clock generator 38 includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded.” (*Appendix E, col. 5, lines 24-26*). The clock generator produces several system clocks, one of which, the ΦC (the main cycle clock), “is the cycle clock for the computer system 10.” (*Appendix E, col. 5, lines 9-14 and 5, lines 27-28*). The “main control logic 26” is a “principle functional section[] of the microcomputer 10.” (*Appendix E, col. 2, lines 63-68*). Within these subsystems “are major buses and major logic elements.” (*Appendix E, col. 18, lines 4-8*).

(Appendix E, Figure 1).

The microprogrammed computer 10 further discloses I/O ports 12, 14, 16, and 18 – referred to as ports 0, 1, 4, and 5. (*Appendix E, col. 3, lines 14-19*). Dozier teaches a test mode, whereby information on one of the ports is immediately fed into the data bus. Specifically, in test mode “port 5 will take the information existing on its pins and drive it into the internal data bus [which] permits port 5 to be a dedicated input to the internal data bus.” (*Appendix E, col. 3, lines 62-66*). Conversely, in test mode “the I/O port 4 logic block will take the data from the data bus and supply it directly to its output pins at all times. This operation is not synchronized with the Φ C clock.” (*Appendix E, col. 3, lines 54-57*) (*emphasis added*).

B. The Dozier Reference Anticipates Claims 1-10 of the '336 Patent

The '336 patent claims the same functionality described above in connection with the Dozier reference. The patent claims a microprocessor system comprising a single integrated circuit that includes a ring oscillator and a central processing unit (CPU), where the ring

oscillator clocks the CPU. (*Appendix A, Claim 1*). The claimed ring oscillator and CPU include a plurality of electronic devices that are constructed of the same process technology so that the frequency of the central processing unit and the speed of the ring oscillator vary together. (*Appendix A, Claim 1*). The claimed integrated circuit also includes an on-chip input/output interface, to which a second clock independent of the ring oscillator is connected. (*Appendix A, Claim 1*).

This is precisely the functionality taught by the Dozier reference. Dozier teaches a microcomputer implemented on a single chip that includes a main control logic clocked by an internal oscillator. Within these subsystems “are major buses and major logic elements.” The Patent Owner has asserted in correspondence with third parties that an internal oscillator indicates the presence of a ring oscillator and that a CPU and an oscillator on the same chip are constructed of the same process technology. Further, Dozier teaches a test mode, whereby information on the ports is immediately fed into and out of the data bus, a form of serial communication which, according to the Patent Owner, satisfies the limitation of a second clock signal.

Detailed correspondence between the Dozier reference and claims 1-10 of the ‘336 patent is shown in the claim chart in section D below.

C. The Dozier Reference, in Light of the Mostek, Kato, and Ledzius References, Renders Obvious Claims 1-10 of the ‘336 Patent

In addition to Dozier’s anticipation of the ‘336 patent described above, the Dozier reference, when viewed in light of the Mostek, Kato, and Ledzius references, further renders obvious several of the limitations already taught by Dozier.

It would have been obvious to one skilled in the art to modify the Dozier teachings to add a serial I/O port, as recited by the independent claims of the ‘336 patent. This is because such functionality is taught by Mostek, a chip specification that is almost identical to the Dozier reference in all other respects. Mostek clearly teaches a “Serial Input/Output Port [which] consists of a serial Shift Register, baud rate generator, and control logic.” (*Appendix F, page III-105*). Dozier and Mostek share all other significant functionality, namely a “main control logic,” “on-chip oscillator circuit,” and I/O ports 0, 1, 4, and 5. (*Appendix F, page III-114; Figure 1*). Because of these similarities, and because Mostek Corporation is listed as the Assignee of the

Dozier patent, one skilled in the art would naturally combine the teachings of Dozier with those of Mostek. (*Appendix E, Abstract page*).

If one skilled in the art modified the Dozier reference to include the serial I/O port taught by Mostek, the modified Dozier microprocessor would clock the serial I/O port with a second “external clock” that is distinct from the internal oscillator that provides the clock signal to the rest of the circuit, as recited by the independent claims of the ‘336 patent. (*Appendix F, pages III-102 and III-105*).

If one skilled in the art modified the teachings of the Dozier reference to include the serial I/O port taught by Mostek, the modified system would also clock the I/O port with a second clock of fixed frequency, as recited by Claims 2, 4, and 8 of the ‘336 patent. Specifically, Mostek teaches the use of a 3.6864MHz crystal with the second I/O clock. (*Appendix F, page III-109*). Additionally, Mostek notes that “any TTL compatible square wave input can be used to generate the clock for the serial port.” (*Appendix F, page III-110*) (emphasis added). Mostek thus teaches the use of an external clock supplying a fixed frequency square wave.

If one skilled in the art modified the teachings of the Dozier reference to include the serial I/O port taught by Mostek, the modified system would transfer information to and from the main control logic in synchrony with the internal clock, as recited by Claim 5 of the ‘336 patent. Specifically, Mostek describes a machine “short cycle, during which time an op code fetch is performed.” (*Appendix F, pages III-113*). One skilled in the art would understand that Mostek’s main control logic performs the op code fetch. (*Appendix J, page 2019*). The short cycle is based on the time base frequency, which is established by the on-chip oscillator circuit. (*Appendix F, pages III-112 to III-114*). One skilled in the art would have found an apparent reason to combine Mostek with Dozier for reasons discussed above.

If one skilled in the art modified the teachings of the Dozier reference to include the serial I/O port taught by Mostek, the added serial port is “very flexible so that it could be used for other purposes such as an interface to . . . serial memory devices.” (*Appendix F, page III-102, col. 1*). Connecting the I/O interface between the central processing unit and an external memory bus is a limitation recited by Claims 6 and 10 of the ‘336 patent.

It would have been obvious to one skilled in the art to modify the teachings of the Dozier reference to use a ring oscillator variable speed system clock as the internal oscillator, as recited

by the independent claims of the '336 patent. This is because such use of a ring oscillator is taught by the Kato reference, which, similar to Dozier, describes a single integrated circuit containing a central processing unit and an oscillator. (*Appendix H, col. 10, line 65 to col. 11, line 7*). One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Dozier's oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (*Appendix H, col. 11, lines 2-7*).

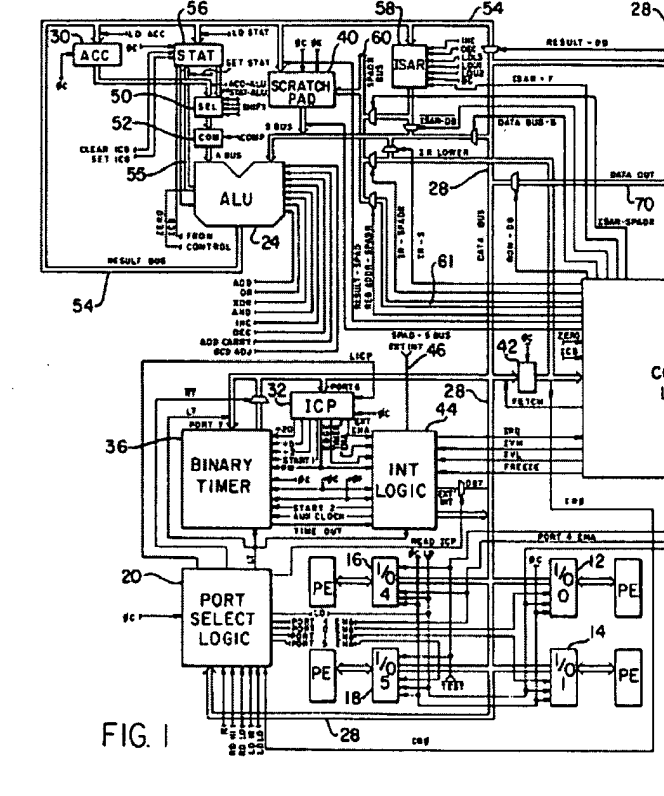

If one skilled in the art modified the teachings of Dozier to use a ring oscillator variable speed system clock as taught by Kato, the output frequency of the clock would lower "in proportion to the speed of the data processing circuit," as recited by the independent claims of the '336 patent. (*Appendix H, col. 11, lines 2-7*)

It would have been obvious to one skilled in the art to modify the teachings of the Dozier reference to use the "same batch and section of semiconductor wafer" in order to create corresponding manufacturing variations, as recited by the independent claims of the '336 patent. (*Appendix I, col. 4, lines 11-12*). This is because the Ledzius reference, which so teaches, is also an integrated circuit with a CPU and an on-chip clock. (*Appendix I, Abstract*).

It would have been obvious to one skilled in the art to modify the teachings of the Dozier reference so that the "frequency of the clock signal produced by [the clock generator] varies to reflect process and temperature variances," as recited by the independent claims of the '336 patent. (*Appendix I, col. 4, lines 9-14*). This is because it would have been obvious to create the circuit of Dozier from the "same batch and section of semiconductor wafer" as taught by Ledzius. (*Id.*)

D. Claim Chart Setting Forth the Correspondence Between the Dozier Reference and Claims 1-10 of the '336 Patent

As described herein, the Dozier reference (*Appendix E*) taken alone or in light of the Mostek, Kato, or Ledzius references raises substantial new questions of patentability for all claims of the '336 patent. The following claim chart demonstrates that all elements in claims 1-10 are anticipated or rendered obvious by the Dozier reference.

<p>Claim Limitation</p> <p>1. A microprocessor system, comprising a single integrated circuit</p>	<p>Teaching of the Dozier Reference</p> <p>The Dozier reference (US Patent No. 4,348,743) teaches a “microprogrammed computer 10 which may be implemented by MOS/LSI techniques and which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63</i>).</p> <p>Dozier teaches a “main control logic unit” that “directs the operations of the entire computer.” (<i>Appendix E, col. 1, lines 46-64; 18, lines 1-14</i>). This main control logic is clearly displayed in Figure 1.</p>  <p style="text-align: center;">(Appendix E, Figure 1).</p>
<p>including a central processing unit and</p>	<p>an entire ring oscillator variable speed system clock in said single integrated circuit and</p>
<p>Dozier teaches a “main control logic unit” that “directs the operations of the entire computer.” (<i>Appendix E, col. 1, lines 46-64; 18, lines 1-14</i>). This main control logic is clearly displayed in Figure 1.</p>	<p>Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded.” (<i>Appendix E, col. 5, lines 24-26</i>).</p> <p>As noted above, the Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art</p>
<p>an entire ring oscillator variable speed system clock in said single integrated circuit and</p>	<p>Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded.” (<i>Appendix E, col. 5, lines 24-26</i>).</p> <p>As noted above, the Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today's processors, would also be true with regard to the processor taught by Dozier. Accordingly, if the office accepts this premise, one skilled in the art would have understood Dozier to disclose a ring oscillator for clocking the central processing unit.</p> <p>Alternatively, this feature is obvious in view of United States Patent No. 4,766,567 to Kato. Kato describes a ring oscillator that can be used to supply clock signals for the main control logic described in Dozier. This is because Kato similarly describes a "one-chip semiconductor device" (<i>Appendix H, col. 1, lines 6-9</i>) that utilizes a ring oscillator because the device "need not have a very accurate frequency." (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). The ring oscillator's "output frequency lowers in proportion to the speed of the data processing circuit which is lowered due to the drop of power supply voltage." (<i>Appendix H, col. 11, lines 1-5</i>). One skilled in the art would have seen an apparent reason to implement the variable speed oscillator of Dozier as Kato's ring oscillator, namely because a ring oscillator is an obvious selection for an internal oscillator. One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Dozier's oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
connected to said central processing unit for clocking said central processing unit,	<p>Figure 1 in Dozier clearly shows clock generator 38 connected to the Main Control Logic. (<i>Appendix E, Figure 1</i>). Further, Dozier teaches that the signal generated by the internal oscillator "is the cycle clock from the computer system 10." The main control logic is described as a "principal functional section[] of the microcomputer." (<i>Appendix E, col. 2, lines 63-68</i>).</p>
said central processing unit and said ring oscillator variable speed system clock each including a plurality of electronic devices	<p>Dozier teaches that "[w]ithin every subsystem of the computer 10 are major buses and major logic elements." (<i>Appendix E, col. 18, lines 4-8</i>).</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
correspondingly constructed of the same process technology with	<p>As explained above, Dozier teaches a microprocessor system fabricated on a single chip, which would necessarily be constructed by a single process technology.</p>

Claim Limitation	Teaching of the Dozier Reference
corresponding manufacturing variations,	<p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Dozier, namely to produce the processor of Dozier with minimal cost and defects.</p>
a processing frequency capability of said central processing unit and a speed of said ring oscillator variable speed system clock varying together due to said manufacturing variations and due to at least operating voltage and temperature of said single integrated circuit;	<p>The Patent Owner has stated in correspondence to various third parties that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the <u>same integrated circuit</u>” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>) (<i>emphasis added</i>).</p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Dozier teaches that the entire “microprogrammed computer 10,” which contains the clock generator 38 and the main control logic 26, “may be implemented by MOS/LSI techniques and [] may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63; see Figure 2</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Dozier, namely to produce the processor of Dozier with minimal cost and defects.</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>Additionally and as described previously, one skilled in the art would see an apparent reason to combine the ring oscillator of Kato with Dozier. In such case, Kato teaches that “[w]hen a ring oscillator is used, its output frequency lowers in proportion to the speed of the data processing circuit, which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 2-7</i>).</p> <p>Further, IC Master discloses a microcomputer that varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%. One skilled in the art would combine IC Master with Dozier because both references teach a “main control logic” that is clocked by an “internal oscillator” which is activated when both the XTL 1 and XTL 2 pins are grounded. (<i>Appendix E, col. 5, lines 24-26; Appendix J, pages 2025-2026</i>).</p>
<p>an on-chip input/output interface connected to exchange coupling control signals, addresses and data with said central processing unit;</p>	<p>Dozier teaches four “input/output ports” 0, 1, 4, and 5 (labeled as 12, 14, 16, and 18 in Figure 1). (<i>Appendix E, col. 3, line 12; Figure 1</i>). These ports are described as “principal functional sections of the microcomputer 10,” “which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-68</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, see for example the Mostek reference. Mostek clearly teaches a “Serial Input/Output Port [which] consists of a serial Shift Register, baud rate generator, and control logic.” (<i>Appendix F, page III-105</i>). This is a simple addition to the functionality shared between Dozier and Mostek, namely a “main control logic,” “on-chip oscillator circuit,” and I/O ports 0, 1, 4, and 5. (<i>Appendix F, page III-114; Figure 1</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier, namely because the chip taught by Mostek is almost identical to the chip taught by the Dozier reference and because Mostek Corporation is listed as the Assignee of the Dozier patent (thus creating a practical presumption that the technologies are compatible). (<i>Appendix E, Abstract page</i>).</p>
<p>and a second clock independent of said ring oscillator variable speed system clock connected to said input/output interface.</p>	<p>The Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). Dozier teaches a test mode, whereby information on one of the ports is immediately fed into the data bus at a rate not synchronized with the clock generator, a form of serial communication which, according to the Patent Owner, satisfies the limitation of a second independent clock signal. Specifically, in test mode “port 5 will take the information existing on its pins and drive it into the internal data bus</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>[which] permits port 5 to be a dedicated input to the internal data bus.” (<i>Appendix D, col. 3, lines 62-66</i>). Likewise, “the I/O port 4 logic block will take the data from the data bus and supply it directly to its output pins at all times. This operation is <u>not synchronized</u> with the ΦC clock.” (<i>Appendix D, col. 3, lines 54-57</i>) (<i>emphasis added</i>). Therefore, Dozier meets this claim limitation according to the technical assertions made by the Patent Owner</p> <p>Alternatively, Requester submits that one skilled in the art would have found an apparent reason to combine Dozier with Mostek’s serial I/O port. Mostek teaches that “[d]ata is shifted into or out of the shift register at a rate determined by [an] external clock.” (<i>Appendix F, page III-105</i>). The serial I/O port clocking signal “is derived from the SRCLK pulse. The SRCLK pulse . . . may be programmed as an input.” (<i>Appendix F, page III-105</i>). Mostek’s main control unit is clocked by the separate, independent “on-chip oscillator circuit.” (<i>Appendix F, pages III-114 to III-115; Figure 1 at page III-103</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier because the chip taught by Mostek is almost identical to the chip taught by the Dozier reference and because Mostek Corporation is listed as the Assignee of the Dozier patent (thus creating a practical presumption that the technologies are compatible).</p> <p>In any case, Requestor notes that the use of a second independent clock for providing clocking signals to an I/O interface was commonplace at the time of filing. (See, e.g., <i>US Patent Nos. 4,443,845 (col. 17, lines 1-42; figs. 14A-14B)</i>; <i>4,409,665 (col. 5, lines 46-6, line 41; fig. 3c)</i>; <i>4,053,946 (col. 34, lines 15-31)</i>; <i>4,868,784 (col. 25, Table I, “Serial-clock control”)</i>; <i>5,142,637 (col. 6, line 59 to col. 7, line 5; col. 7, line 63 to col. 8, line 2; Figs. 12 & 13)</i>).</p>
Claim 2	
2. The microprocessor system of claim 1 in which said second clock is a fixed frequency clock.	<p>Dozier teaches that while in test mode, “an external tester may be utilized to input test signals on the internal data bus through port 5.” (<i>Appendix E, col. 4, lines 1-4</i>). One skilled in the art would recognize that this external tester transmits data into port 5 at a fixed frequency.</p> <p>Alternatively, Requester submits that one skilled in the art would have found an apparent reason to combine Dozier with Mostek’s I/O port. Mostek teaches the use of a fixed frequency 3.6864MHz crystal with the second I/O clock. (<i>Appendix F, page III-109</i>). Additionally, Mostek notes that “<u>any</u> TTL compatible square wave input can be used to generate the clock for the serial port.” (<i>Appendix F, page III-110</i>) (<i>emphasis added</i>).</p>
Claim 3	
3. In a microprocessor integrated circuit,	The Dozier reference (US Patent No. 4,348,743) teaches a “microprogrammed computer 10 which may be implemented by MOS/LSI

Claim Limitation	Teaching of the Dozier Reference
	techniques and which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63</i>).
<p>a method for clocking the microprocessor within the integrated circuit, comprising the steps of:</p> <p>providing an entire ring oscillator system clock</p>	<p>Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded.” (<i>Appendix E, col. 5, lines 24-26</i>).</p> <p>The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today’s processors, would also be true with regard to the processor taught by Dozier. Accordingly, if the office accepts this premise, one skilled in the art would have understood Dozier to disclose a ring oscillator for clocking the central processing unit.</p> <p>Alternatively, this feature is obvious in view of United States Patent No. 4,766,567 to Kato. Kato describes a ring oscillator that can be used to supply clock signals for the main control logic described in Dozier. This is because Kato similarly describes a “one-chip semiconductor device” (<i>Appendix H, col. 1, lines 6-9</i>) that utilizes a ring oscillator because the device “need not have a very accurate frequency.” (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). The ring oscillator’s “output frequency lowers in proportion to the speed of the data processing circuit which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 1-5</i>). One skilled in the art would have seen an apparent reason to implement the variable speed oscillator of Dozier as Kato’s ring oscillator, namely because a ring oscillator is an obvious selection for an internal oscillator. One skilled in the art would realize the benefits of implementing Kato’s ring oscillator as Dozier’s oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
constructed of electronic devices within the integrated circuit,	<p>Dozier teaches that “[w]ithin every subsystem of the computer 10 are major buses and major logic elements.” (<i>Appendix E, col. 18, lines 4-8</i>).</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>

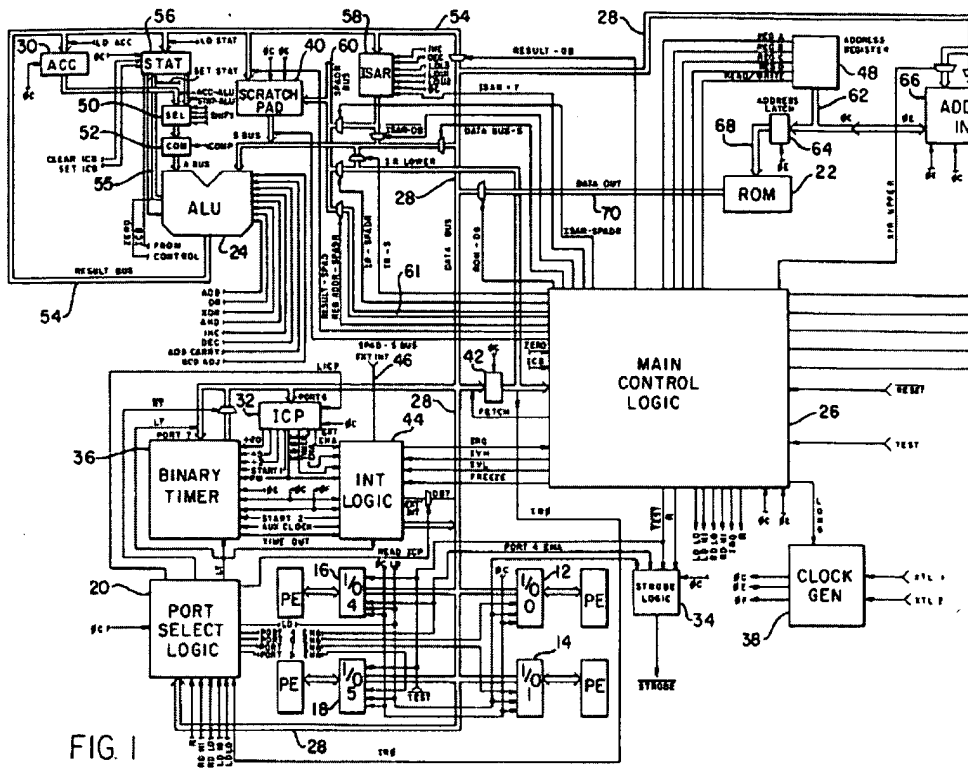

Claim Limitation	Teaching of the Dozier Reference
<p>said electronic devices having operating characteristics which will, because said entire ring oscillator system clock and said microprocessor are located within the same integrated circuit, vary together with operating characteristics of electronic devices included within the microprocessor;</p>	<p>As explained above, Dozier teaches a microprocessor system fabricated on a single chip, which would necessarily be constructed by a single process technology.</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the <u>same integrated circuit</u>” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>) (<i>emphasis added</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Dozier, namely to produce the processor of Dozier with minimal cost and defects.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Dozier teaches that the entire “microprogrammed computer 10,” which contains the clock generator 38 and the main control logic 26, “may be implemented by MOS/LSI techniques and [] may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63; see Figure 2</i>).</p> <p>Additionally and as described previously, one skilled in the art would see an apparent reason to combine the ring oscillator of Kato with Dozier. In such case, Kato teaches that “[w]hen a ring oscillator is used, its output frequency lowers in proportion to the speed of the data processing circuit, which is lowered due to the drop of power supply voltage.” (<i>Appendix H,</i></p>

Claim Limitation	Teaching of the Dozier Reference
	<p><i>col. 11, lines 2-7).</i></p> <p>Further, IC Master discloses a microcomputer that varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%. One skilled in the art would combine IC Master with Dozier because both references teach a “main control logic” that is clocked by an “internal oscillator” which is activated when both the XTL 1 and XTL 2 pins are grounded. (<i>Appendix E, col. 5, lines 24-26; Appendix J, pages 2025-2026</i>).</p>
<p>using the ring oscillator system clock for clocking the microprocessor,</p>	<p>As explained above, Dozier teaches clocking the microprocessor with on-chip oscillator.</p>
<p>said microprocessor operating at a variable processing frequency dependent upon a variable speed of said ring oscillator system clock;</p>	<p>The Patent Owner has stated in correspondence to various third parties that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the <u>same integrated circuit</u>” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>) (<i>emphasis added</i>).</p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Dozier teaches that the entire “microprogrammed computer 10,” which contains the clock generator 38 and the main control logic 26, “may be implemented by MOS/LSI techniques and [] may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63; see Figure 2</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Dozier, namely to produce the processor of Dozier with minimal cost and defects.</p> <p>Additionally and as described previously, one skilled in the art would see an</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>apparent reason to combine the ring oscillator of Kato with Dozier. In such case, Kato teaches that “[w]hen a ring oscillator is used, its output frequency lowers in proportion to the speed of the data processing circuit, which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 2-7</i>).</p> <p>Further, IC Master discloses a microcomputer that varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%. One skilled in the art would combine IC Master with Dozier because both references teach a “main control logic” that is clocked by an “internal oscillator” which is activated when both the XTL 1 and XTL 2 pins are grounded. (<i>Appendix E, col. 5, lines 24-26; Appendix J, pages 2025-2026</i>).</p>
providing an on chip input/output interface for the microprocessor integrated circuit; and	<p>Dozier teaches four “input/output ports” 0, 1, 4, and 5 (labeled as 12, 14, 16, and 18 in Figure 1). (<i>Appendix E, col. 3, line 12; Figure 1</i>). These ports are described as “principal functional sections of the microcomputer 10,” “which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-68</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, see for example the Mostek reference. Mostek clearly teaches a “Serial Input/Output Port [which] consists of a serial Shift Register, baud rate generator, and control logic.” (<i>Appendix F, page III-105</i>). This is a simple addition to the functionality shared between Dozier and Mostek, namely a “main control logic,” “on-chip oscillator circuit,” and I/O ports 0, 1, 4, and 5. (<i>Appendix F, page III-114; Figure 1</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier, namely because the chip taught by Mostek is almost identical to the chip taught by the Dozier reference and because Mostek Corporation is listed as the Assignee of the Dozier patent (thus creating a practical presumption that the technologies are compatible). (<i>Appendix E, Abstract page</i>).</p>
clocking the input/output interface with a second clock independent of the ring oscillator system clock,	<p>The Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). Dozier teaches a test mode, whereby information on one of the ports is immediately fed into the data bus at a rate not synchronized with the clock generator, a form of serial communication which, according to the Patent Owner, satisfies the limitation of a second independent clock signal. Specifically, in test mode “port 5 will take the information existing on its pins and drive it into the internal data bus [which] permits port 5 to be a dedicated input to the internal data bus.” (<i>Appendix D, col. 3, lines 62-66</i>). Likewise, “the I/O port 4 logic block will</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>take the data from the data bus and supply it directly to its output pins at all times. This operation is <u>not synchronized</u> with the ΦC clock.” (<i>Appendix D, col. 3, lines 54-57</i>) (<i>emphasis added</i>). Therefore, Dozier meets this claim limitation according to the technical assertions made by the Patent Owner</p> <p>Alternatively, Requester submits that one skilled in the art would have found an apparent reason to combine Dozier with Mostek’s serial I/O port would teach the features of this limitation. Mostek teaches that “[d]ata is shifted into or out of the shift register at a rate determined by [an] external clock.” (<i>Appendix F, page III-105</i>). The serial I/O port clocking signal “is derived from the SRCLK pulse. The SRCLK pulse . . . may be programmed as an input.” (<i>Appendix F, page III-105</i>). Mostek’s main control unit is clocked by the separate, independent “on-chip oscillator circuit.” (<i>Appendix F, pages III-114 to III-115; Figure 1 at page III-103</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier because the chip taught by Mostek is almost identical to the chip taught by the Dozier reference and because Mostek Corporation is listed as the Assignee of the Dozier patent (thus creating a practical presumption that the technologies are compatible).</p> <p>In any case, Requestor notes that the use of a second independent clock for providing clocking signals to an I/O interface was commonplace at the time of filing. (<i>See, e.g., US Patent Nos. 4,443,845 (col. 17, lines 1-42; figs. 14A-14B); 4,409,665 (col. 5, lines 46-6, line 41; fig. 3c); 4,053,946 (col. 34, lines 15-31); 4,868,784 (col. 25, Table I, “Serial-clock control”); 5,142,637 (col. 6, line 59 to col. 7, line 5; col. 7, line 63 to col. 8, line 2; Figs. 12 & 13)</i>).</p>
Claim 4	
<p>4. The method of claim 3 in which the second clock is a fixed frequency clock.</p>	<p>Dozier teaches that while in test mode, “an external tester may be utilized to input test signals on the internal data bus through port 5.” (<i>Appendix E, col. 4, lines 1-4</i>). One skilled in the art would recognize that this external tester transmits data into port 5 at a fixed frequency.</p> <p>Alternatively, Requester submits that one skilled in the art would have found an apparent reason to combine Dozier with Mostek’s I/O port. Mostek teaches the use of a fixed frequency 3.6864MHz crystal with the second I/O clock. (<i>Appendix F, page III-109</i>). Additionally, Mostek notes that “<u>any</u> TTL compatible square wave input can be used to generate the clock for the serial port.” (<i>Appendix F, page III-110</i>) (<i>emphasis added</i>).</p>
Claim 5	
<p>5. The method of claim 3 further including the step of:</p>	<p>One skilled in the art would understand that information is transferred to the main control logic at a frequency determined by the internal oscillator: Figure 1 in Dozier clearly shows clock generator 38 connected to the Main</p>

Claim Limitation	Teaching of the Dozier Reference
<p>transferring information to and from said microprocessor in synchrony with said ring oscillator system clock.</p>	<p>Control Logic. (<i>Appendix E, Figure 1</i>). Further, Dozier teaches that the signal generated by the internal oscillator “is the cycle clock from the computer system 10.” The main control logic is described as a “principal functional section[] of the microcomputer.” (<i>Appendix E, col. 2, lines 63-68</i>).</p> <p>Alternatively, this feature is obvious in view of the Mostek reference. Mostek describes a machine “short cycle, during which time an op code fetch is performed.” (<i>Appendix F, pages III-113</i>). One skilled in the art would understand that Mostek’s main control logic performs the op code fetch. (<i>Appendix J, page 2019</i>). The short cycle is based on the time base frequency, which is established by the on-chip oscillator circuit. (<i>Appendix F, pages III-112 to III-114</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier for reasons discussed above.</p>
Claim 6	
<p>6. A microprocessor system comprising: a central processing unit disposed upon an integrated circuit substrate, said central processing unit operating at a processing frequency</p>	<p>The Dozier reference (US Patent No. 4,348,743) teaches a “microprogrammed computer 10 which may be implemented by MOS/LSI techniques and which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63</i>).</p> <p>Dozier teaches a “main control logic unit” that “directs the operations of the entire computer.” (<i>Appendix E, col. 1, lines 46-64; 18, lines 1-14</i>). This main control logic is clearly displayed in Figure 1.</p>

Claim Limitation	Teaching of the Dozier Reference
	 <p>FIG. 1</p> <p>(Appendix E, Figure 1).</p> <p>Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded” for clocking the microprocessor. (Appendix E, col. 5, lines 24-26).</p>
<p>and being constructed of a first plurality of electronic devices;</p>	<p>Dozier teaches that “[w]ithin every subsystem of the computer 10 are major buses and major logic elements.” (Appendix E, col. 18, lines 4-8).</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
<p>an entire oscillator disposed upon said integrated circuit substrate and connected to said central processing unit, said oscillator</p>	<p>Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded.” (Appendix E, col. 5, lines 24-26). Dozier teaches producing the “clock signal ΦC” for clocking the microprocessor. (Appendix E, col. 3, line 26)</p>

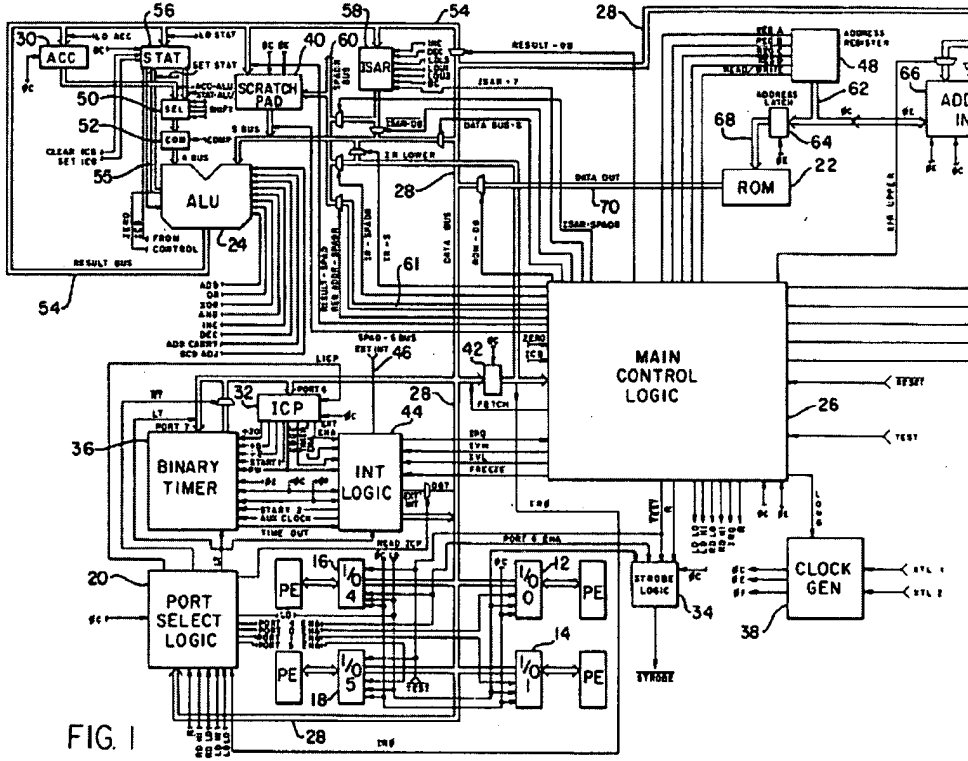

Claim Limitation	Teaching of the Dozier Reference
clocking said central processing unit at a clock rate and	
being constructed of a second plurality of electronic devices,	<p>Dozier teaches that “[w]ithin every subsystem of the computer 10 are major buses and major logic elements.” (<i>Appendix E, col. 18, lines 4-8</i>).</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
<p>thus varying the processing frequency of said first plurality of electronic devices and the clock rate of said second plurality of electronic devices in the same way as a function of parameter variation in one or more fabrication or operational parameters associated with said integrated circuit substrate, thereby enabling said processing frequency to track said clock rate in response to said parameter variation;</p>	<p>As explained above, Dozier teaches a microprocessor system fabricated on a single chip, which would necessarily be constructed by a single process technology.</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the <u>same integrated circuit</u>” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>) (<i>emphasis added</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Dozier, namely to produce the processor of Dozier with minimal cost and defects.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Dozier teaches that the entire “microprogrammed computer 10,” which contains the clock generator 38 and the main control logic 26, “may be implemented by MOS/LSI techniques and [] may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63; see Figure 2</i>).</p> <p>Additionally and as described previously, one skilled in the art would see an apparent reason to combine the ring oscillator of Kato with Dozier. In such case, Kato teaches that “[w]hen a ring oscillator is used, its output frequency lowers in proportion to the speed of the data processing circuit, which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 2-7</i>).</p> <p>Further, IC Master discloses a microcomputer that varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%. One skilled in the art would combine IC Master with Dozier because the chip taught by IC Master is in the same family of processors as the chip taught by the Dozier reference. (<i>Appendix E, col. 5, lines 24-26; Appendix J, pages 2025-2026</i>).</p>
<p>an on-chip input/output interface, connected between said said [sic] central processing unit and an external memory bus, for facilitating exchanging coupling control signals, addresses and data with said central processing unit; and</p>	<p>Dozier teaches four “input/output ports” 0, 1, 4, and 5 (labeled as 12, 14, 16, and 18 in Figure 1). (<i>Appendix E, col. 3, line 12; Figure 1</i>). These ports are described as “principal functional sections of the microcomputer 10,” “which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-68</i>).</p> <p>Dozier teaches that the control sections of computers often transmit data “into some output device to be stored on another storage media.” (<i>Appendix E, col. 1:56-61</i>). The input/output ports of the microprogrammed computer taught by Dozier specifically disclose communicating with peripheral devices. (<i>Appendix E, col. 4, lines 28-29</i>).</p> <p>Alternatively, this feature is obvious in view of the Mostek reference. Mostek teaches that the serial port is “very flexible so that it could be used for other purposes such as an interface to . . . serial memory devices.” (<i>Appendix F, page III-102, col. 1</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier for reasons discussed above.</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, see for example the Mostek reference. Mostek clearly teaches a “Serial Input/Output Port [which] consists of a serial Shift Register, baud</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>rate generator, and control logic.” (<i>Appendix F, page III-105</i>). This is a simple addition to the functionality shared between Dozier and Mostek, namely a “main control logic,” “on-chip oscillator circuit,” and I/O ports 0, 1, 4, and 5. (<i>Appendix F, page III-114; Figure 1</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier, namely because the chip taught by Mostek is almost identical to the chip taught by the Dozier reference and because Mostek Corporation is listed as the Assignee of the Dozier patent (thus creating a practical presumption that the technologies are compatible). (<i>Appendix E, Abstract page</i>).</p>
<p>an external clock, independent of said oscillator, connected to said input/output interface wherein said external clock is operative at a frequency independent of a clock frequency of said oscillator.</p>	<p>The Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). Dozier teaches a test mode, whereby information on one of the ports is immediately fed into the data bus at a rate not synchronized with the clock generator, a form of serial communication which, according to the Patent Owner, satisfies the limitation of a second independent clock signal. Specifically, in test mode “port 5 will take the information existing on its pins and drive it into the internal data bus [which] permits port 5 to be a dedicated input to the internal data bus.” (<i>Appendix D, col. 3, lines 62-66</i>). Likewise, “the I/O port 4 logic block will take the data from the data bus and supply it directly to its output pins at all times. This operation is <u>not synchronized</u> with the ΦC clock.” (<i>Appendix D, col. 3, lines 54-57</i>) (<i>emphasis added</i>). Therefore, Dozier meets this claim limitation according to the technical assertions made by the Patent Owner</p> <p>Moreover, Requester submits that one skilled in the art would have found an apparent reason to combine Dozier with Mostek’s serial I/O port. Mostek teaches that “[d]ata is shifted into or out of the shift register at a rate determined by [an] external clock.” (<i>Appendix F, page III-105</i>). The serial I/O port clocking signal “is derived from the SRCLK pulse. The SRCLK pulse . . . may be programmed as an input.” (<i>Appendix F, page III-105</i>). Mostek’s main control unit is clocked by the separate, independent “on-chip oscillator circuit.” (<i>Appendix F, pages III-114 to III-115; Figure 1 at page III-103</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier for reasons discussed above.</p> <p>In any case, Requestor notes that the use of a second independent clock for providing clocking signals to an I/O interface was commonplace at the time of filing. (<i>See, e.g., US Patent Nos. 4,443,845 (col. 17, lines 1-42; figs. 14A-14B); 4,409,665 (col. 5, lines 46-6, line 41; fig. 3c); 4,053,946 (col. 34, lines 15-31); 4,868,784 (col. 25, Table I, “Serial-clock control”); 5,142,637 (col. 6, line 59 to col. 7, line 5; col. 7, line 63 to col. 8, line 2; Figs. 12 & 13)</i>).</p>

Claim Limitation Claim 7	Teaching of the Dozier Reference
<p>7. The microprocessor system of claim 6 wherein said one or more operational parameters include operating temperature of said substrate or operating voltage of said substrate.</p>	<p>The Patent Owner has stated in correspondence to various third parties that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the <u>same integrated circuit</u>” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>) (<i>emphasis added</i>).</p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Dozier teaches that the entire “microprogrammed computer 10,” which contains the clock generator 38 and the main control logic 26, “may be implemented by MOS/LSI techniques and [] may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63; see Figure 2</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Dozier, namely to produce the processor of Dozier with minimal cost and defects.</p> <p>Further, IC Master discloses a microcomputer that varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%. One skilled in the art would combine IC Master with Dozier because the chip taught by IC Master is in the same family of processors as the chip taught by the Dozier reference. (<i>Appendix E, col. 5, lines 24-26; Appendix J, pages 2025-2026</i>).</p>
Claim 8	
<p>8. The microprocessor system of claim 6 wherein said external clock comprises a fixed-frequency clock which operates synchronously relative to said</p>	<p>The test mode taught by Dozier describes a tester placing information onto the pins and therefore having it directly driven onto the data bus at a clock rate that is synchronized with the internal clock cycle. Specifically, “the strobe logic unit 34 is to provide a synchronizing clock to an external tester during the test mode to indicate what machine cycle the computer is in . . . so that [the tester] can coordinate the forcing of information onto the data bus.” (<i>Appendix E, col. 4, lines 34-45</i>).</p>

Claim Limitation	Teaching of the Dozier Reference
oscillator.	<p>As an aside, the Requester notes that this limitation is also taught by Kato. Kato teaches a microprocessor system having two clock. The first clock generator clocks the CPU and the second clock generator is connected to the I/O port. (<i>Appendix H, col. 4, lines 37-42 and FIG. 4</i>)</p> <p>Kato teaches that the first and second clock generators operate synchronously: “second clock generator 15 produces two clock signals ϕ_a and ϕ_b... Signals ϕ_a and ϕ_b are produced in synchronism with the signal from first clock generator 14.” (<i>Appendix H, col. 4, lines 56-60</i>) As explained above, one skilled in the art would have found an apparent reason to combine the teachings of Kato and Mostek, namely to provide Mostek with a ring oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
Claim 9	
9. The microprocessor system of claim 6 wherein said oscillator comprises a ring oscillator.	<p>The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today’s processors, would also be true with regard to the processor taught by Dozier. Accordingly, if the office accepts this premise, one skilled in the art would have understood Dozier to disclose a ring oscillator for clocking the central processing unit.</p> <p>Alternatively, this feature is obvious in view of United States Patent No. 4,766,567 to Kato. Kato describes a ring oscillator that can be used to supply clock signals for the main control logic described in Dozier. This is because Kato similarly describes a “one-chip semiconductor device” (<i>Appendix H, col. 1, lines 6-9</i>) that utilizes a ring oscillator because the device “need not have a very accurate frequency.” (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). The ring oscillator’s “output frequency lowers in proportion to the speed of the data processing circuit which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 1-5</i>). One skilled in the art would have seen an apparent reason to implement the variable speed oscillator of Dozier as Kato’s ring oscillator, namely because a ring oscillator is an obvious selection for an internal oscillator. One skilled in the art would realize the benefits of implementing Kato’s ring oscillator as Dozier’s oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix</i></p>

Claim Limitation	Teaching of the Dozier Reference
	<i>H, col. 11, lines 2-7).</i>
Claim 10	
<p>10. In a microprocessor system including a central processing unit, a method for clocking said central processing unit comprising the steps of:</p>	<p>The Dozier reference (US Patent No. 4,348,743) teaches a “microprogrammed computer 10 which may be implemented by MOS/LSI techniques and which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63</i>).</p> <p>Dozier teaches a “main control logic unit” that “directs the operations of the entire computer.” (<i>Appendix E, col. 1, lines 46-64; 18, lines 1-14</i>). This main control logic is clearly displayed in Figure 1.</p>  <p>FIG. 1</p> <p>(<i>Appendix E, Figure 1</i>).</p> <p>Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded” for clocking the microprocessor. (<i>Appendix E, col. 5, lines 24-26</i>).</p>
<p>providing said central processing unit upon</p>	<p>As described above, Dozier teaches a “microprogrammed computer 10 which may be implemented by MOS/LSI techniques and which may be</p>

Claim Limitation	Teaching of the Dozier Reference
an integrated circuit substrate,	fabricated on a single semiconductor chip.” (Appendix E, col. 2, lines 60-63).
said central processing unit being constructed of a first plurality of transistors and being operative at a processing frequency;	<p>See Dozier teaches that “[w]ithin every subsystem of the computer 10 are major buses and major logic elements.” (Appendix E, col. 18, lines 4-8).</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p> <p>Dozier teaches producing the “clock signal ΦC” for clocking the microprocessor. (Appendix E, col. 3, line 26)</p>
providing an entire variable speed clock disposed upon said integrated circuit substrate,	<p>Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded.” (Appendix E, col. 5, lines 24-26). Dozier teaches producing the “clock signal ΦC” for clocking the microprocessor. (Appendix E, col. 3, line 26)</p> <p>The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today’s processors; would also be true with regard to the processor taught by Dozier. Accordingly, if the office accepts this premise, one skilled in the art would have understood Dozier to disclose a ring oscillator for clocking the central processing unit.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (Appendix I, col. 4, lines 3-21). Dozier teaches that the entire “microprogrammed computer 10,” which contains the clock generator 38 and the main control logic 26, “may be implemented by MOS/LSI techniques and [] may be fabricated on a single semiconductor chip.” (Appendix E, col. 2, lines 60-63; see Figure 2).</p> <p>Additionally and as described previously, one skilled in the art would see an apparent reason to combine the ring oscillator of Kato with Dozier. In such case, Kato teaches that “[w]hen a ring oscillator is used, its output frequency lowers in proportion to the speed of the data processing circuit, which is lowered due to the drop of power supply voltage.” (Appendix H, col. 11, lines 2-7):</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>Further, IC Master discloses a microcomputer that varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%. One skilled in the art would combine IC Master with Dozier because the chip taught by IC Master is in the same family of processors as the chip taught by the Dozier reference. (<i>Appendix E, col. 5, lines 24-26; Appendix J, pages 2025-2026</i>).</p>
<p>said variable speed clock being constructed of a second plurality of transistors;</p>	<p>Dozier teaches that “[w]ithin every subsystem of the computer 10 are major buses and major logic elements.” (<i>Appendix E, col. 18, lines 4-8</i>).</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
<p>clocking said central processing unit at a clock rate using said variable speed clock</p>	<p>As described above, Dozier teaches a “clock generator 38 [that] includes an internal oscillator which is activated when both the XTL 1 and XTL 2 pins are grounded.” (<i>Appendix E, col. 5, lines 24-26</i>). Dozier teaches producing the “clock signal ΦC” for clocking the microprocessor. (<i>Appendix E, col. 3, line 26</i>)</p>
<p>with said central processing unit being clocked by said variable speed clock at a variable frequency dependent upon variation in one or more fabrication or operational parameters associated with said integrated circuit substrate, said processing frequency and said clock rate varying in the same way relative to said variation in said one or more fabrication or operational parameters associated with said integrated circuit substrate;</p>	<p>As explained above, Dozier teaches a microprocessor system fabricated on a single chip, which would necessarily be constructed by a single process technology.</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the <u>same integrated circuit</u>” causes the microprocessor and clock to necessarily “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>) (<i>emphasis added</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Dozier, namely to produce the processor of Dozier with minimal cost and defects.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Dozier teaches that the entire “microprogrammed computer 10,” which contains the clock generator 38 and the main control logic 26, “may be implemented by MOS/LSI techniques and [] may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-63; see Figure 2</i>).</p> <p>Additionally and as described previously, one skilled in the art would see an apparent reason to combine the ring oscillator of Kato with Dozier. In such case, Kato teaches that “[w]hen a ring oscillator is used, its output frequency lowers in proportion to the speed of the data processing circuit, which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 2-7</i>).</p> <p>Further, IC Master discloses a microcomputer that varies in frequency from 1.7-4MHz when operating from its internal oscillator due in part to a varying ambient temperature range of 0-70 °C and a varying VCC of +5V +/- 10%. One skilled in the art would combine IC Master with Dozier is in the same family of processors. (<i>Appendix E, col. 5, lines 24-26; Appendix J, pages 2025-2026</i>).</p>
<p>connecting an on chip input/output interface between said central processing unit and an external memory bus, and exchanging coupling control signals, addresses and data between said input/output interface and said central processing unit; and</p>	<p>Dozier teaches four “input/output ports” 0, 1, 4, and 5 (labeled as 12, 14, 16, and 18 in Figure 1). (<i>Appendix E, col. 3, line 12; Figure 1</i>). These ports are described as “principal functional sections of the microcomputer 10,” “which may be fabricated on a single semiconductor chip.” (<i>Appendix E, col. 2, lines 60-68</i>).</p> <p>Dozier teaches that the control sections of computers often transmit data “into some output device to be stored on another storage media.” (<i>Appendix E, col. 1:56-61</i>). The input/output ports of the microprogrammed computer taught by Dozier specifically disclose communicating with peripheral devices. (<i>Appendix E, col. 4, lines 28-29</i>).</p> <p>Alternatively, this feature is obvious in view of the Mostek reference. Mostek teaches that the serial port is “very flexible so that it could be used</p>

Claim Limitation	Teaching of the Dozier Reference
	<p>for other purposes such as an interface to . . . serial memory devices.” (<i>Appendix F, page III-102, col. 1</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier for reasons discussed above.</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, see for example the Mostek reference. Mostek clearly teaches a “Serial Input/Output Port [which] consists of a serial Shift Register, baud rate generator, and control logic.” (<i>Appendix F, page III-105</i>). This is a simple addition to the functionality shared between Dozier and Mostek, namely a “main control logic,” “on-chip oscillator circuit,” and I/O ports 0, 1, 4, and 5. (<i>Appendix F, page III-114; Figure 1</i>). One skilled in the art would have found an apparent reason to combine Mostek with Dozier, namely because the chip taught by Mostek is almost identical to the chip taught by the Dozier reference and because Mostek Corporation is listed as the Assignee of the Dozier patent (thus creating a practical presumption that the technologies are compatible). (<i>Appendix E, Abstract page</i>).</p>
clocking said input/output interface using an external clock wherein said external clock is operative at a frequency independent of a clock frequency of said variable speed clock.	See teachings corresponding to Claim 1.

From the foregoing chart, it can be seen that claims 1-10 are anticipated and rendered obvious by Dozier. Thus, claims 1-10 are unpatentable as being anticipated under 35 U.S.C. § 102(b) and/or obvious under U.S.C. § 103 in view of the Mostek, Kato, or Ledzius references.

E. The Dozier Reference Anticipates or Renders Obvious the Newly Introduced Claims of the ‘336 Patent

The Dozier reference anticipates or renders obvious new claims added during the patent’s ongoing merged reexamination. The Patent Owner added claims 11-20 which parallel respective original claims 1-10 except that they further include a limitation to “more clearly set forth the meaning of ‘independent.’” (*Appendix C, Amendment, Sept. 8, 2008, original page 11*). The

additional limitations append the parallel independent claims and recite: “thereby enabling decoupling a speed of said central processing unit from a speed of said input/output interface.” (*Id.*).

Specifically, Dozier teaches the test mode discussed above, whereby information on the data bus is immediately fed to one of the ports and conversely, information on another port is immediately fed into the data, a form of serial communication which, according to the Patent Owner, satisfies the limitation of a second clock signal. (*Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8*). “This operation is not synchronized with the Φ C clock,” which indicates a decoupling of speed of this serial communication from the speed of the main control logic. (*Appendix D, col. 3, lines 54-57*) (*emphasis added*).

In any case, if one skilled in the art modified the Dozier reference to include the serial I/O port taught by Mostek, Dozier would also be modified to include a second clock connected to the serial input/output port. Specifically, the serial input/output port taught by Mostek is clocked by an “external clock” that is distinct and decoupled in speed from the internal oscillator that provides the clock signal to the rest of the circuit. (*Appendix F, pages III-102 and III-105*).

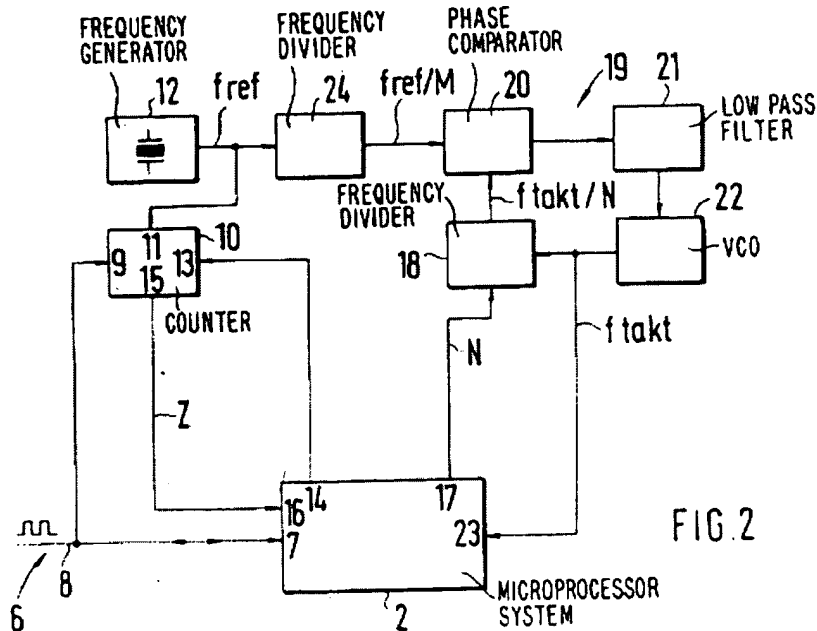

X. THE RICHTER REFERENCE ANTICIPATES OR RENDERS OBVIOUS CLAIMS 1-10 OF THE ‘336 PATENT

The prior art references provided in this request raise substantial new questions of patentability as to claims 1-10 of the ‘336 patent. Specifically, all claims are anticipated by the Richter reference and additionally rendered obvious over Richter in light of the McDermott reference, the Ledzius reference, or the Kato reference.

A. Summary of the Teachings of the Richter Reference

The Richter reference teaches a system for adapting the speed of a serial interface of a data processing system to the data transmission speed of a communication partner. (*Appendix D, col. 1, lines 46-60*). More specifically, this system consists of a microprocessor system 2 which is connected to several other microprocessor systems via a bus system. (*Appendix D, col. 2, lines 32-36*). The reference teaches an arrangement in which the microprocessor will “adjust itself to the individual transmission speeds of the respective communicating partners.” (*Appendix D, col.*

2, lines 50-54). It is contemplated to provide the microprocessor system 2 “in a one-chip system” with a microprocessor, RAM and ROM memory chips, a serial interface, and “other chips required for their operation.” (*Appendix D, col. 2, lines 63-65*). In some embodiments, the voltage controlled oscillator is “required” for the operation of the microprocessor.

(*Appendix D, Figure 2*)

The circuit functions to operate the serial interface at the same frequency as the signals arriving at the interface. Specifically, a counter 10 counts signals that arrive on signal line 8 and informs the microprocessor system of the result at input 16. (*Appendix D, col. 3, lines 1-10*). The microprocessor system outputs a signal N on output 17 into a phase locking loop 19, which drives the signal for a voltage controlled oscillator 22. (*Appendix D, col. 3, lines 11-17*). “The voltage controlled oscillator 22 generates a clock pulse “ f_{takt} ” that acts upon the microprocessor system 2 through clock frequency input 23.” (*Appendix D, col. 3, lines 18-20*). Due also to the input of a signal from a frequency generator 12, the “ f_{takt} ” signal settles upon an equilibrium of “ $(N/M) * f_{ref}$ ” where M is fixed and N is the signal output to the phase locking loop by the microprocessor system. (*Appendix D, col. 3, lines 67 through col. 4, line 13*). The signal “ f_{takt} ” is used in various embodiments to clock the serial transmission interface. (*Appendix D, col. 4,*

lines 34-43). In one embodiment, Richter teaches that a “a separate system clock generator” that is independent of the “ftakt” signal may serve as the system clock for the microprocessor 2. (*Appendix D, col. 4, lines 34-43*).

B. The Richter Reference Anticipates Claims 1-10 of the ‘336 Patent

The ‘336 patent claims the same functionality described above in connection with the Richter reference. The patent teaches a single integrated circuit “microprocessor system” that includes a ring oscillator which clocks a central processing unit. (*Appendix A, Claim 1*). These components are claimed to include a plurality of devices and be “constructed of the same process technology” so that the speed of the central processing unit and the ring oscillator vary together. (*Appendix A, Claim 1*). The integrated circuit must also include an “on-chip input/output interface,” to which a second clock independent of the ring oscillator is connected. (*Appendix A, Claim 1*).

This claimed functionality is taught by the Richter reference. Richter teaches a voltage controlled oscillator, a microprocessor, and an I/O port that may be provided in a “single-chip” system. In some embodiments the voltage controlled oscillator clocks both the serial I/O port and the microprocessor. Richter teaches additional embodiments where the microprocessor is clocked by a “separate system clock generator.” It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator. The Patent Owner has asserted in communication with various third parties that a voltage controlled oscillator is the equivalent of a ring oscillator. Further, the Patent Owner has asserted that an oscillator and a central processing unit provided on the same chip both include a plurality of devices and vary in speed together.

Detailed correspondence between the Richter reference and claims 1-10 of the ‘336 patent is shown in the claim chart in section D below.

C. The Richter Reference, in Light of the McDermott, Ledzius, and Kato References, Renders Obvious Claims 1-10 of the ‘336 Patent

In addition to Richter’s anticipation of the ‘336 patent described above, the McDermott, Ledzius, and Kato references, when viewed in light of the Richter reference, further render obvious several of the limitations already taught by Richter.

It would have been obvious for one skilled in the art to modify the teachings of Richter so that a voltage controlled oscillator that clocks the microprocessor was included on the one-chip system, as recited by the independent '336 claims. This is because U.S. Patent No. 4,931,748 (the "McDermott" reference) teaches a "voltage controlled oscillator" that resides on a "single integrated circuit" and clocks the entire microcomputer. (*Appendix G, cols. 3, lines 17-21; 3, lines 57-63; and 4, lines 24-29*). It would have been obvious to combine the Richter and McDermott references because both references teach a single chip integrated circuit containing a central processing unit and a serial interface, where this central processing unit is clocked by a voltage controlled oscillator. (*Appendix G, col. 3, lines 17-21*).

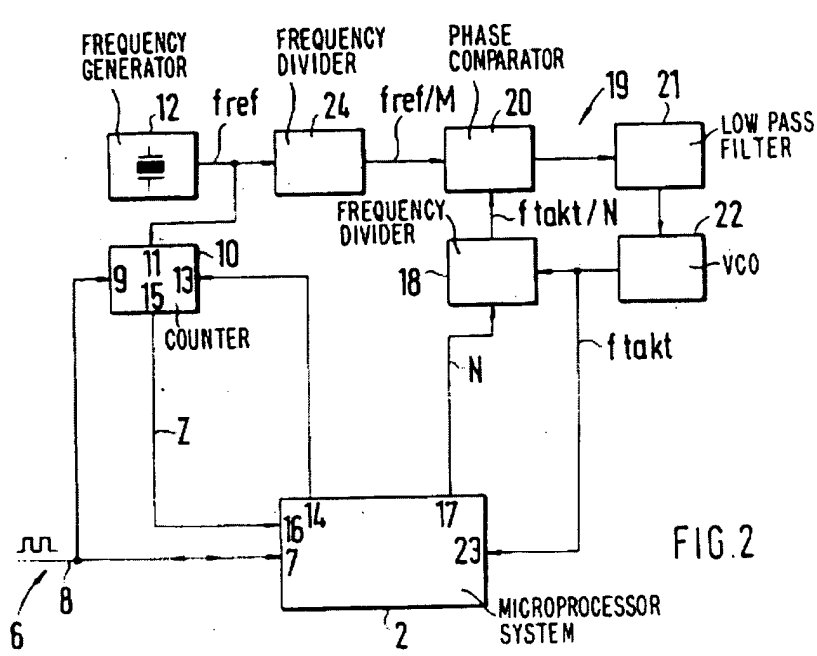

It would have been obvious to one skilled in the art to modify the teachings of the Richter reference to use a ring oscillator variable speed system clock as the internal oscillator, as recited by the independent claims of the '336 patent. This is because such use of a ring oscillator is taught by the Kato reference, which, similar to Richter, describes a single integrated circuit containing a central processing unit and an oscillator. (*Appendix H, col. 10, lines 65 through 11, lines 7*). One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Richter's variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (*Appendix H, col. 11, lines 2-7*).

It would have been obvious for one skilled in art to modify the teachings of the Richter reference to use the "same batch and section of semiconductor wafer" in order to create "corresponding manufacturing variations" so that the speed of the ring oscillator and the system clock vary together, as recited by the independent '336 claims. (*Appendix I, col. 4, lines 11-12*). This is because the Ledzius reference, which so teaches, is also an integrated circuit with a central processing unit and an on-chip clock. (*Appendix I, Abstract*).

D. Claim Chart Setting Forth the Correspondence Between the Richter Reference and Claims 1-10 of the '336 Patent

As described herein, the Richter reference (*Appendix D*), alone or in light of the McDermott, Ledzius, or Kato references, raises substantial new questions of patentability for all claims of the '336 patent. The following claim chart demonstrates that all elements in claims 1-10 are anticipated or rendered obvious by the Richter reference.

Claim Limitation	Teaching of the Richter Reference
------------------	-----------------------------------

Claim Limitation	Teaching of the Richter Reference
Claim 1	
1. A microprocessor system, comprising a single integrated circuit	<p>The Richter reference (U.S. Patent No. 4,853,841) teaches a “microprocessor system 2” that is contemplated to provide the functions of a microprocessor, RAM, ROM, a serial interface, and a parallel interface where “in a one-chip system.” (<i>Appendix D, col. 2, lines 55-65</i>).</p>  <p style="text-align: right;">FIG. 2</p> <p style="text-align: center;">(<i>Appendix D, Figure 2</i>).</p>
including a central processing unit and	Richter teaches that the “microprocessor system” includes a “microprocessor.” (<i>Appendix D, col. 2, lines 55-65</i>).
an entire ring oscillator variable speed system clock in said single integrated circuit and connected to said central processing unit for clocking said central processing unit,	<p>Richter teaches that a “voltage-controlled oscillator generates a clock pulse ‘ftakt’ that acts upon the microprocessor system.” (<i>Appendix D, col. 3, lines 18-20</i>). In some embodiments the ‘ftakt’ signal is used as both the system clock and a clock for the I/O port. (<i>Appendix D, col. 4, lines 34-43</i>). In other embodiments Richter teaches that the microprocessor is clocked by a “separate system clock generator for the microprocessor 2.” (<i>Appendix D, col. 4, lines 34-38</i>). It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator in a different embodiment.</p> <p>The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip</p>

Claim Limitation	Teaching of the Richter Reference
	<p>clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today's processors, would also be true with regard to the processor taught by Richter. Accordingly, if the office accepts this premise, one skilled in the art would have understood Richter to disclose a ring oscillator for clocking the central processing unit.</p> <p>Alternatively, this feature is obvious in view of United States Patent No. 4,766,567 to Kato ("Kato"). Kato describes a ring oscillator that can be used to supply clock signals for the CPU described in Richter. (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). One skilled in the art would have seen an apparent reason to implement Kato's ring oscillator as the voltage controlled oscillator or separate system clock of Richter, namely because a ring oscillator is an obvious selection for an internal oscillator and Richter already teaches the use of a voltage controlled oscillator to clock the microprocessor. One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Richter's variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p> <p>Further, Richter teaches that the voltage-controlled oscillator may be provided in the one-chip microprocessor system. Specifically, "[t]he first microprocessor system 2 is, for example, set up in a configuration comprising the microprocessor, volatile (RAM) and nonvolatile (ROM) memory chips, the serial interface and parallel input/output chips as well as other chips required for their operation. It is also contemplated to provide all these functions in a one-chip system." (<i>Appendix D, col. 2, lines 59-66</i>). The voltage-controlled oscillator, along with most of the other components displayed in Figure 2, are required for the operation of the microprocessor, and thus Richter teaches providing them on the one-chip system.</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,931,748 to McDermott et al. McDermott teaches a "voltage controlled oscillator" that resides on a "single integrated circuit" and clocks the entire microcomputer. (<i>Appendix G, col. 3, lines 17-21 and 57-63; col. 4, lines 24-29</i>). Both Richter and McDermott teach a single chip integrated circuit containing a central processing unit and a serial interface, where the central processing unit is clocked by a voltage controlled oscillator. (<i>Appendix G, col. 3, lines 17-21</i>). One skilled in the art would have found an apparent reason to combine</p>

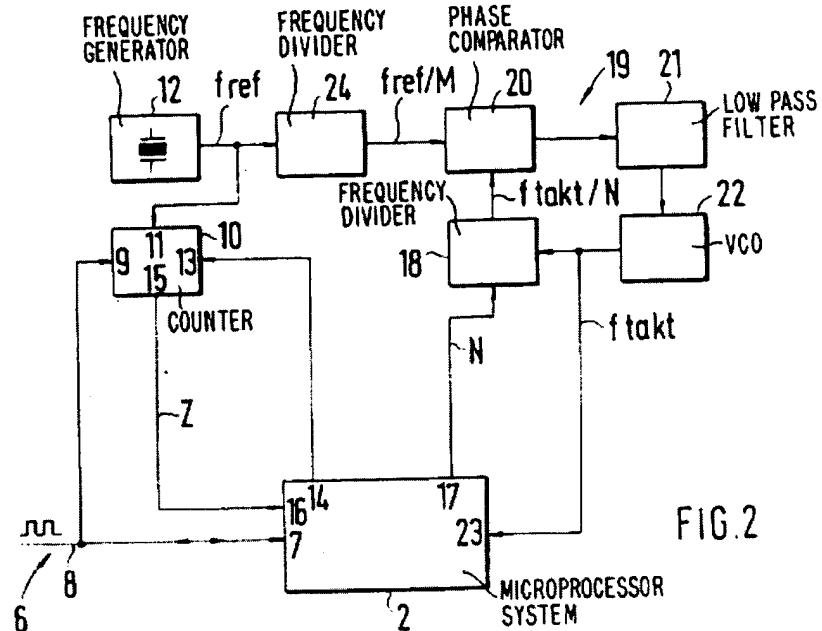

Claim Limitation	Teaching of the Richter Reference
	<p>Richter with McDermott, namely to provide the processor of Richter with a voltage controlled oscillator capable of generating clock signals across a wide range of frequencies.</p>
<p>said central processing unit and said ring oscillator variable speed system clock each including a plurality of electronic devices correspondingly constructed of the same process technology with corresponding manufacturing variations,</p>	<p>One skilled in the art would understand the on-chip oscillator circuit and the main control logic to include a plurality of electronic devices.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p> <p>With respect to the limitation of the CPU and ring oscillator being constructed of the same process technology, Richter teaches implementing the microprocessor “in a one-chip system.” (<i>Appendix D, col. 2, lines 55-65</i>), which would necessarily be constructed by a single process technology. This indicates that the oscillator is fabricated on the same chip as the CPU and that the oscillator and CPU would therefore be constructed by the same process technology. (<i>Appendix F, page III-114</i>)</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the processor of Richter with minimal cost and defects.</p>
<p>a processing frequency capability of said central processing unit and a speed of said ring oscillator variable speed system clock</p>	<p>The Patent Owner has stated in correspondence to various third parties that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p>

Claim Limitation	Teaching of the Richter Reference
<p>varying together due to said manufacturing variations and due to at least operating voltage and temperature of said single integrated circuit;</p>	<p>Further, during the examination of the '336 patent, the Applicant stated that "the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit" causes the microprocessor and clock to naturally "vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance." (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6.</i>)</p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the "same batch and section of semiconductor wafer" results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Richter contemplates providing all the chips required for the microprocessor's functioning on a "one-chip system." (<i>Appendix D, col. 2, lines 59-66</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the one-chip system of Richter with minimal cost and defects.</p>
<p>an on-chip input/output interface connected to exchange coupling control signals, addresses and data with said central processing unit;</p>	<p>Richter teaches that the "microprocessor system 2 has a serial interface (not shown) which is connected by the input/output port 7 to a signal line 8 of the serial bus system 6." (<i>Appendix D, col. 2, lines 55-58</i>).</p>
<p>and a second clock independent of said ring oscillator variable speed system clock connected to said input/output interface.</p>	<p>Richter teaches a signal "ftakt" for clocking the serial I/O port of the microprocessor that is independent of the CPU clock: "the data transmission of the serial interface is supplied with the clock frequency signal 'ftakt', and the microprocessor of the microprocessor system 2 is equipped with its own system clock generator." (<i>Col. 4, lines 34-43 and 58-62</i>) Richter describes the system clock as a "separate system clock generator for the microprocessor" that is independent of the I/O clock signal. (<i>Col. 4, lines 36-47</i>)</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). As previously described, Richter clearly teaches a serial interface. If the Patent Owner's assertions are true today as to commercial processors, then they are also true as to the prior art processors.</p>

Claim Limitation	Teaching of the Richter Reference
	<p>In any case, Requestor notes that the use of a second independent clock for providing clocking signals to an I/O interface was commonplace at the time of filing. (See, e.g., <i>US Patent Nos. 4,443,845 (col. 17, lines 1-42; figs. 14A-14B)</i>; <i>4,409,665 (col. 5, lines 46-6, lines 41; fig. 3c)</i>; <i>4,053,946 (col. 34, lines 15-31)</i>; <i>4,868,784 (col. 25, Table I, "Serial-clock control")</i>; <i>5,142,637 (col. 6, line 59 to col. 7, line 5; col. 7, line 63 to col. 8, line 2; Figs. 12 & 13)</i>).</p>
Claim 2	
<p>2. The microprocessor system of claim 1 in which said second clock is a fixed frequency clock.</p>	<p>Richter teaches that "[t]he division ratio 1/M at the second frequency divider 24 is fixed. It determines the frequency increments by which the clock frequency signal 'ftakt' can be adjusted. It is fixed such that by means of a programmable, integer value of N, a suitable clock frequency 'ftakt' is adjusted. From this adjusted clock frequency 'ftakt', the desired transmission speeds v' can be derived with a required precision by integer division so that the microprocessor system can therefore be synchronized with the communication partner." (<i>Col. 4, lines 10-19</i>) One skilled in the art would understand that if the communication partner operates at a fixed frequency, the clock signal 'ftakt' would be a fixed frequency clock signal.</p> <p>The clock signal 'ftakt' taught by Richter is based on "clock frequency input 23." (<i>Col. 3, lines 18-20</i>). Requester notes that use of a fixed frequency clock as a clock input was well known in the art at the time of filing. (See, e.g., <i>the Mostek reference (Appendix F, page III-109)</i>; <i>US 4,893,271 (col. 1, lines 17-18)</i>; <i>US 4,751,565 (col. 1, lines 50-52)</i>; <i>US 4,947,411 (Abstract)</i>; <i>US 5,050,195 (Abstract)</i>; <i>US 4,835,491 (col. 2, lines 24-25)</i>)</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). If the Patent Owner's assertions are accepted, one skilled in the art would recognize that the incoming signal to the serial interface could be of fixed frequency, teaching the features of this limitation.</p>
Claim 3	
<p>3. In a microprocessor integrated circuit,</p>	<p>The Richter reference (U.S. Patent No. 4,853,841) teaches a "microprocessor system 2" that is contemplated to provide the functions of a microprocessor, RAM, ROM, a serial interface, and a parallel interface where "in a one-chip system." (<i>Appendix D, col. 2, lines 55-65</i>).</p>

Claim Limitation

Teaching of the Richter Reference

(Appendix D, Figure 2).

a method for clocking the microprocessor within the integrated circuit, comprising the steps of:

providing an entire ring oscillator system clock

Richter teaches that a “voltage-controlled oscillator generates a clock pulse ‘fakt’ that acts upon the microprocessor system.” (*Appendix D, col. 3, lines 18-20*). In some embodiments the ‘fakt’ signal is used as both the system clock and a clock for the I/O port. (*Appendix D, col. 4, lines 34-43*). In other embodiments Richter teaches that the microprocessor is clocked by a “separate system clock generator for the microprocessor 2.” (*Appendix D, col. 4, lines 34-38*). It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator in a different embodiment.

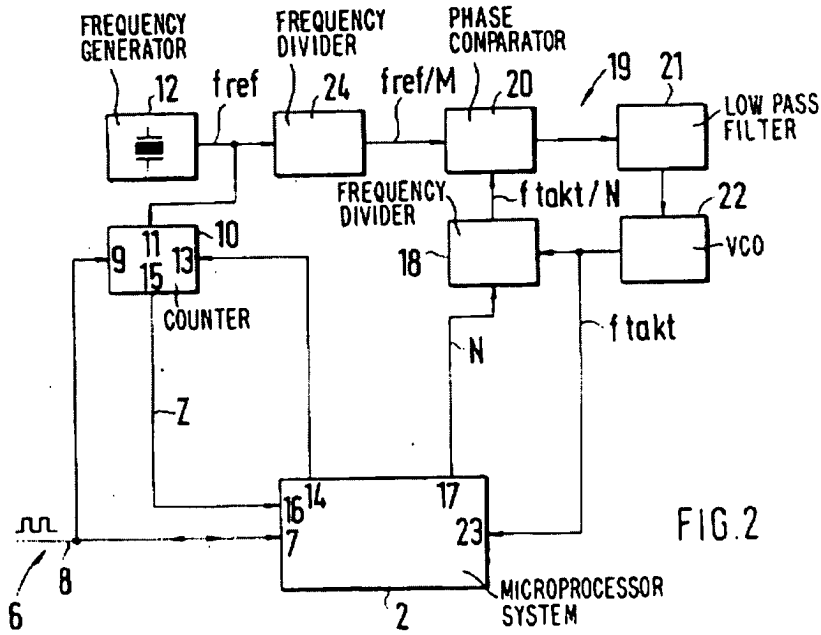

The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today’s processors, would also be true with regard to the processor taught by Richter. Accordingly, if the office accepts this premise, one skilled in the art would have understood Richter to disclose a ring oscillator for clocking the central processing unit.

Claim Limitation	Teaching of the Richter Reference
	<p>Alternatively, this feature is obvious in view of U. S. Patent No. 4,766,567 to Kato ("Kato"). Kato describes a ring oscillator that can be used to supply clock signals for the CPU described in Richter. (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). One skilled in the art would have seen an apparent reason to implement Kato's ring oscillator as the voltage controlled oscillator or separate system clock of Richter, namely because a ring oscillator is an obvious selection for an internal oscillator and Richter already teaches the use of a voltage controlled oscillator to clock the microprocessor. One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Richter's variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p> <p>Further, Richter teaches that the voltage-controlled oscillator may be provided in the one-chip microprocessor system. Specifically, "[t]he first microprocessor system 2 is, for example, set up in a configuration comprising the microprocessor, volatile (RAM) and nonvolatile (ROM) memory chips, the serial interface and parallel input/output chips as well as other chips required for their operation. It is also contemplated to provide all these functions in a one-chip system." (<i>Appendix D, col. 2, lines 59-66</i>). The voltage-controlled oscillator, along with most of the other components displayed in Figure 2, are required for the operation of the microprocessor, and thus Richter teaches providing them on the one-chip system.</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,931,748 to McDermott et al. McDermott teaches a "voltage controlled oscillator" that resides on a "single integrated circuit" and clocks the entire microcomputer. (<i>Appendix G, col. 3, lines 17-21 and 57-63; col. 4, lines 24-29</i>). Both Richter and McDermott teach a single chip integrated circuit containing a central processing unit and a serial interface, where the central processing unit is clocked by a voltage controlled oscillator. (<i>Appendix G, col. 3, lines 17-21</i>). One skilled in the art would have found an apparent reason to combine Richter with McDermott, namely to provide the processor of Richter with a voltage controlled oscillator capable of generating clock signals across a wide range of frequencies.</p>
constructed of electronic devices within the integrated circuit,	<p>One skilled in the art would understand the on-chip oscillator circuit and the main control logic to include a plurality of electronic devices.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
said electronic devices having	Richter teaches implementing the microprocessor "in a one-chip system." (<i>Appendix D, col. 2, lines 55-65</i>), which would necessarily be constructed

Claim Limitation	Teaching of the Richter Reference
<p>operating characteristics which will, because said entire ring oscillator system clock and said microprocessor are located within the same integrated circuit, vary together with operating characteristics of electronic devices included within the microprocessor;</p>	<p>by a single process technology. This indicates that the oscillator is fabricated on the same chip as the CPU and that the oscillator and CPU would therefore be constructed by the same process technology. (<i>Appendix F, page III-114</i>)</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>.)</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the processor of Richter with minimal cost and defects.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Richter contemplates providing all the chips required for the microprocessor’s functioning on a “one-chip system.” (<i>Appendix D, col. 2, lines 59-66</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the one-chip system of Richter with minimal cost and defects.</p>
<p>using the ring oscillator system clock for clocking the microprocessor,</p>	<p>The voltage-controlled oscillator taught by Richter is used to clock the microprocessor as described above.</p>

Claim Limitation	Teaching of the Richter Reference
<p>said microprocessor operating at a variable processing frequency dependent upon a variable speed of said ring oscillator system clock;</p>	<p>The Patent Owner has stated in correspondence to various third parties that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6.</i>)</p> <p>As an aside, Requestor notes that Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Richter contemplates providing all the chips required for the microprocessor’s functioning on a “one-chip system.” (<i>Appendix D, col. 2, lines 59-66</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the one-chip system of Richter with minimal cost and defects.</p> <p>Additionally and as described previously, one skilled in the art would see an apparent reason to combine the ring oscillator of Kato with Richter. In such case, Kato teaches that “[w]hen a ring oscillator is used, its output frequency lowers in proportion to the speed of the data processing circuit, which is lowered due to the drop of power supply voltage.” (<i>Appendix H, col. 11, lines 2-7</i>).</p>
<p>providing an on chip input/output interface for the microprocessor integrated circuit; and</p>	<p>Richter teaches that the “microprocessor system 2 has a serial interface (not shown) which is connected by the input/output port 7 to a signal line 8 of the serial bus system 6.” (<i>Appendix D, col. 2, lines 55-58</i>).</p>
<p>clocking the input/output interface with a second clock independent of the ring oscillator system clock,</p>	<p>Richter teaches a signal “ftakt” for clocking the serial I/O port of the microprocessor that is independent of the CPU clock: “the data transmission of the serial interface is supplied with the clock frequency signal ‘ftakt’, and the microprocessor of the microprocessor system 2 is equipped with its own system clock generator.” (<i>Col. 4, lines 34-43 and 58-62</i>) Richter describes the system clock as a “separate system clock generator for the</p>

Claim Limitation	Teaching of the Richter Reference
	<p>microprocessor” that is independent of the I/O clock signal. (<i>Col. 4, lines 36-47</i>)</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). As previously described, Richter clearly teaches a serial interface. If the Patent Owner’s assertions are true today as to commercial processors, then they are also true as to the prior art processors.</p> <p>In any case, Requestor notes that the use of a second independent clock for providing clocking signals to an I/O interface was commonplace at the time of filing. (<i>See, e.g., US Patent Nos. 4,443,845 (col. 17, lines 1-42; figs. 14A-14B); 4,409,665 (col. 5, lines 46-6, lines 41; fig. 3c); 4,053,946 (col. 34, lines 15-31); 4,868,784 (col. 25, Table I, “Serial-clock control”); 5,142,637 (col. 6, line 59 to col. 7, line 5; col. 7, line 63 to col. 8, line 2; Figs. 12 & 13).</i>)</p>
Claim 4	
<p>4. The method of claim 3 in which the second clock is a fixed frequency clock.</p>	<p>Richter teaches that “[t]he division ratio 1/M at the second frequency divider 24 is fixed. It determines the frequency increments by which the clock frequency signal ‘ftakt’ can be adjusted. It is fixed such that by means of a programmable, integer value of N, a suitable clock frequency ‘ftakt’ is adjusted. From this adjusted clock frequency ‘ftakt’, the desired transmission speeds v’ can be derived with a required precision by integer division so that the microprocessor system can therefore be synchronized with the communication partner.” (<i>Col. 4, lines 10-19</i>) One skilled in the art would understand that if the communication partner operates at a fixed frequency, the clock signal ‘ftakt’ would be a fixed frequency clock signal.</p> <p>The clock signal ‘ftakt’ taught by Richter is based on “clock frequency input 23.” (<i>Col. 3, lines 18-20</i>). Requester notes that use of a fixed frequency clock as a clock input was well known in the art at the time of filing. (<i>See, e.g., the Mostek reference (Appendix F, page III-109); US 4,893,271 (col. 1, lines 17-18); US 4,751,565 (col. 1, lines 50-52); US 4,947,411 (Abstract); US 5,050,195 (Abstract); US 4,835,491 (col. 2, lines 24-25)</i>)</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). If the Patent Owner’s assertions are accepted, one skilled in the art would recognize that the incoming signal to the serial interface could be of fixed frequency, teaching</p>

Claim Limitation	Teaching of the Richter Reference
	the features of this limitation.
Claim 5	
<p>5. The method of claim 3 further including the step of: transferring information to and from said microprocessor in synchrony with said ring oscillator system clock.</p>	<p>As described in the teachings corresponding to Claim 1, a voltage controlled oscillator is taught as a “separate system clock generator for the microprocessor 2.” (<i>Appendix D, col. 4, lines 34-38</i>). One skilled in the art would understand that information is transferred to and from the microprocessor in synchrony with the microprocessor’s system clock.</p>
Claim 6	
<p>6. A microprocessor system comprising: a central processing unit disposed upon an integrated circuit substrate,</p>	<p>The Richter reference (U.S. Patent No. 4,853,841) teaches a “microprocessor system 2” that is contemplated to provide the functions of a microprocessor, RAM, ROM, a serial interface, and a parallel interface where “in a one-chip system.” (<i>Appendix D, col. 2, lines 55-65</i>).</p>  <p style="text-align: right;">FIG. 2</p> <p style="text-align: center;">(Appendix D, Figure 2).</p> <p>Richter teaches that the “microprocessor system” includes a “microprocessor.” (<i>Appendix D, col. 2, lines 55-65</i>).</p>
said central	Richter teaches that a “voltage-controlled oscillator generates a clock pulse

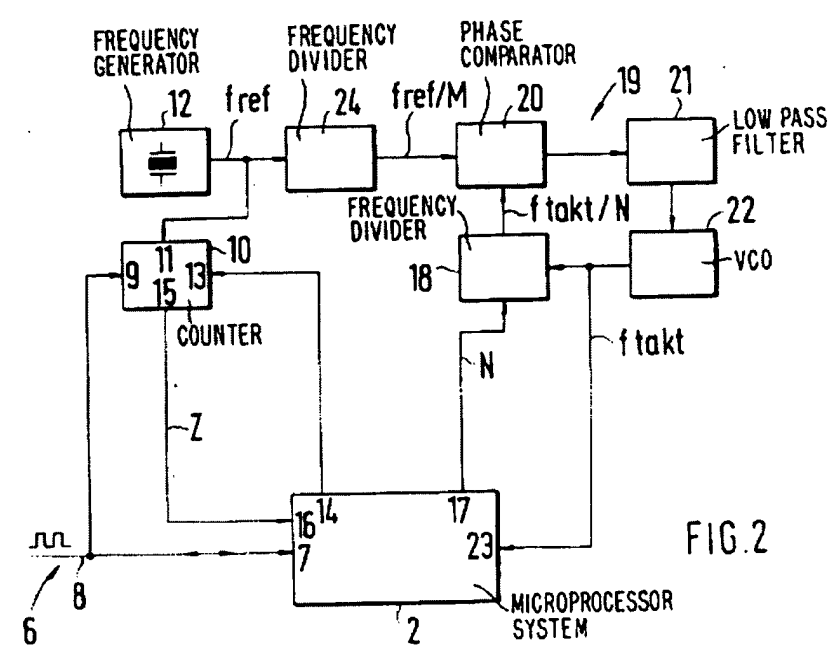

Claim Limitation	Teaching of the Richter Reference
processing unit operating at a processing frequency	‘fakt’ that acts upon the microprocessor system.” (<i>Appendix D, col. 3, lines 18-20</i>). In some embodiments the ‘fakt’ signal is used as both the system clock and a clock for the I/O port. (<i>Appendix D, col. 4, lines 34-43</i>). In other embodiments Richter teaches that the microprocessor is clocked by a “separate system clock generator for the microprocessor 2.” (<i>Appendix D, col. 4, lines 34-38</i>). It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator in a different embodiment. The microprocessor operates at the frequency of the oscillator.
and being constructed of a first plurality of electronic devices;	<p>One skilled in the art would understand the on-chip oscillator circuit and the main control logic to include a plurality of electronic devices.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
an entire oscillator disposed upon said integrated circuit substrate and connected to said central processing unit, said oscillator clocking said central processing unit at a clock rate and	Richter teaches that a “voltage-controlled oscillator generates a clock pulse ‘fakt’ that acts upon the microprocessor system.” (<i>Appendix D, col. 3, lines 18-20</i>). In some embodiments the ‘fakt’ signal is used as both the system clock and a clock for the I/O port. (<i>Appendix D, col. 4, lines 34-43</i>). In other embodiments Richter teaches that the microprocessor is clocked by a “separate system clock generator for the microprocessor 2.” (<i>Appendix D, col. 4, lines 34-38</i>). It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator in a different embodiment. The microprocessor operates at the frequency of the oscillator.
being constructed of a second plurality of electronic devices,	<p>One skilled in the art would understand the on-chip oscillator circuit and the main control logic to include a plurality of electronic devices.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of electronic devices.</p>
thus varying the processing frequency of said first plurality of electronic devices and the clock rate of said second plurality of electronic devices in the same way as a	<p>Richter teaches implementing the microprocessor “in a one-chip system.” (<i>Appendix D, col. 2, lines 55-65</i>), which would necessarily be constructed by a single process technology. This indicates that the oscillator is fabricated on the same chip as the CPU and that the oscillator and CPU would therefore be constructed by the same process technology. (<i>Appendix F, page III-114</i>)</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to</p>

Claim Limitation	Teaching of the Richter Reference
<p>function of parameter variation in one or more fabrication or operational parameters associated with said integrated circuit substrate, thereby enabling said processing frequency to track said clock rate in response to said parameter variation;</p>	<p>various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6</i>.)</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the processor of Richter with minimal cost and defects.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Richter contemplates providing all the chips required for the microprocessor’s functioning on a “one-chip system.” (<i>Appendix D, col. 2, lines 59-66</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the one-chip system of Richter with minimal cost and defects.</p>
<p>an on-chip input/output interface, connected between said said [sic] central processing unit and an external memory bus, for facilitating exchanging coupling control signals, addresses and data</p>	<p>Richter teaches that the “microprocessor system 2 has a serial interface (not shown) which is connected by the input/output port 7 to a signal line 8 of the serial bus system 6.” (<i>Appendix D, col. 2, lines 55-58</i>).</p> <p>Richter teaches that the serial interface is connected to other microprocessor systems which contain various types of memory. (<i>Appendix D, col. 2, lines 32-68</i>).</p>

Claim Limitation	Teaching of the Richter Reference
with said central processing unit; and	
<p>an external clock, independent of said oscillator, connected to said input/output interface wherein said external clock is operative at a frequency independent of a clock frequency of said oscillator.</p>	<p>Richter teaches a signal “ftakt” for clocking the serial I/O port of the microprocessor that is independent of the CPU clock: “the data transmission of the serial interface is supplied with the clock frequency signal ‘ftakt’, and the microprocessor of the microprocessor system 2 is equipped with its own system clock generator.” (<i>Col. 4, lines 34-43 and 58-62</i>) Richter describes the system clock as a “separate system clock generator for the microprocessor” that is independent of the I/O clock signal. (<i>Col. 4, lines 36-47</i>)</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). As previously described, Richter clearly teaches a serial interface. If the Patent Owner’s assertions are true today as to commercial processors, then they are also true as to the prior art processors.</p> <p>In any case, Requestor notes that the use of a second independent clock for providing clocking signals to an I/O interface was commonplace at the time of filing. (<i>See, e.g., US Patent Nos. 4,443,845 (col. 17, lines 1-42; figs. 14A-14B); 4,409,665 (col. 5, lines 46-6, lines 41; fig. 3c); 4,053,946 (col. 34, lines 15-31); 4,868,784 (col. 25, Table I, “Serial-clock control”); 5,142,637 (col. 6, line 59 to col. 7, line 5; col. 7, line 63 to col. 8, line 2; Figs. 12 & 13)</i>).</p>
Claim 7	
<p>7. The microprocessor system of claim 6 wherein said one or more operational parameters include operating temperature of said substrate or operating voltage of said substrate.</p>	<p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various</p>

Claim Limitation	Teaching of the Richter Reference
	<p>parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6.</i>)</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the processor of Richter with minimal cost and defects.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Richter contemplates providing all the chips required for the microprocessor’s functioning on a “one-chip system.” (<i>Appendix D, col. 2, lines 59-66</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the one-chip system of Richter with minimal cost and defects.</p>
Claim 8	
<p>8. The microprocessor system of claim 6 wherein said external clock comprises a fixed-frequency clock which operates synchronously relative to said oscillator.</p>	<p>Richter teaches that “[t]he division ratio 1/M at the second frequency divider 24 is fixed. It determines the frequency increments by which the clock frequency signal ‘ftakt’ can be adjusted. It is fixed such that by means of a programmable, integer value of N, a suitable clock frequency ‘ftakt’ is adjusted. From this adjusted clock frequency ‘ftakt’, the desired transmission speeds v’ can be derived with a required precision by integer division so that the microprocessor system can therefore be synchronized with the communication partner.” (Col. 4, lines 10-19) One skilled in the art would understand that if the communication partner operates at a fixed frequency, the clock signal ‘ftakt’ would be a fixed frequency clock signal.</p> <p>The clock signal ‘ftakt’ taught by Richter is based on “clock frequency input 23.” (Col. 3, lines 18-20). Requester notes that use of a fixed frequency clock as a clock input was well known in the art at the time of filing. (See, e.g., the Mostek reference (<i>Appendix F, page III-109</i>); US 4,893,271 (col. 1, lines 17-18); US 4,751,565 (col. 1, lines 50-52); US 4,947,411 (Abstract); US 5,050,195 (Abstract); US 4,835,491 (col. 2, lines 24-25))</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8). If the Patent Owner’s assertions are accepted, one skilled in the art would recognize that the</p>

Claim Limitation	Teaching of the Richter Reference
	<p>incoming signal to the serial interface could be of fixed frequency, teaching the features of this limitation.</p> <p>Richter teaches one embodiment where the system reaches a point of equilibrium so that frequency of the voltage controlled oscillator is synchronous to the frequency of the serial data transmission. (<i>Appendix D, Abstract</i>).</p> <p>As an aside, the Requester notes that this limitation is also taught by Kato. Kato teaches a microprocessor system having two clock. The first clock generator clocks the CPU and the second clock generator is connected to the I/O port. (<i>Appendix H, col. 4, lines 37-42 and FIG. 4</i>)</p> <p>Kato teaches that the first and second clock generators operate synchronously: "second clock generator 15 produces two clock signals ϕ_a and ϕ_b... Signals ϕ_a and ϕ_b are produced in synchronism with the signal from first clock generator 14." (<i>Appendix H, col. 4, lines 56-60</i>) As explained above, one skilled in the art would have found an apparent reason to combine the teachings of Kato and Mostek, namely to provide Mostek with a ring oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
Claim 9	
<p>9. The microprocessor system of claim 6 wherein said oscillator comprises a ring oscillator.</p>	<p>The Patent Owner has asserted in correspondence to various third parties that all on-chip oscillators are variable and that the presence of an on-chip clock generation circuit indicates the presence of a ring oscillator (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). The Requester notes that the functionality of prior art processors are the same in material respect to commercial processors referred to by the Patent Owner in the above mentioned communications to third parties. Therefore, such an allegation, if true with respect to today's processors, would also be true with regard to the processor taught by Richter. Accordingly, if the office accepts this premise, one skilled in the art would have understood Richter to disclose a ring oscillator for clocking the central processing unit.</p> <p>Alternatively, this feature is obvious in view of U. S. Patent No. 4,766,567 to Kato ("Kato"). Kato describes a ring oscillator that can be used to supply clock signals for the CPU described in Richter. (<i>Appendix H, col. 10, line 64 to col. 11, line 7</i>). One skilled in the art would have seen an apparent reason to implement Kato's ring oscillator as the voltage controlled oscillator or separate system clock of Richter, namely because a ring oscillator is an obvious selection for an internal oscillator and Richter already teaches the use of a voltage controlled oscillator to clock the</p>

Claim Limitation	Teaching of the Richter Reference
	<p>microprocessor. One skilled in the art would realize the benefits of implementing Kato's ring oscillator as Richter's variable oscillator to reduce power consumption during periods of lessened processing demand and to increase clock speed (and power consumption) during periods of increased processing demand. (<i>Appendix H, col. 11, lines 2-7</i>).</p>
Claim 10	
<p>10. In a microprocessor system including a central processing unit, a method for clocking said central processing unit comprising the steps of:</p>	<p>The Richter reference (U.S. Patent No. 4,853,841) teaches a "microprocessor system 2" that is contemplated to provide the functions of a microprocessor, RAM, ROM, a serial interface, and a parallel interface where "in a one-chip system." (<i>Appendix D, col. 2, lines 55-65</i>).</p>  <p style="text-align: right;">FIG. 2</p> <p style="text-align: center;">(<i>Appendix D, Figure 2</i>).</p> <p>Richter teaches that the "microprocessor system" includes a "microprocessor." (<i>Appendix D, col. 2, lines 55-65</i>).</p>
<p>providing said central processing unit upon an integrated circuit substrate,</p>	<p>Richter teaches a microprocessor system implemented as a "one-chip system" as described above.</p>
<p>said central processing unit being constructed of a first plurality of transistors</p>	<p>One skilled in the art would understand the on-chip oscillator circuit and the main control logic to include a plurality of transistors.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third</p>

Claim Limitation	Teaching of the Richter Reference
and	parties that all CPUs and clocks inherently include a plurality of transistors.
being operative at a processing frequency;	Richter teaches that a “voltage-controlled oscillator generates a clock pulse ‘ftakt’ that acts upon the microprocessor system.” (<i>Appendix D, col. 3, lines 18-20</i>). In some embodiments the ‘ftakt’ signal is used as both the system clock and a clock for the I/O port. (<i>Appendix D, col. 4, lines 34-43</i>). In other embodiments Richter teaches that the microprocessor is clocked by a “separate system clock generator for the microprocessor 2.” (<i>Appendix D, col. 4, lines 34-38</i>). It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator in a different embodiment. The microprocessor operates at the frequency of the oscillator.
providing an entire variable speed clock disposed upon said integrated circuit substrate,	Richter teaches that a “voltage-controlled oscillator generates a clock pulse ‘ftakt’ that acts upon the microprocessor system.” (<i>Appendix D, col. 3, lines 18-20</i>). In some embodiments the ‘ftakt’ signal is used as both the system clock and a clock for the I/O port. (<i>Appendix D, col. 4, lines 34-43</i>). In other embodiments Richter teaches that the microprocessor is clocked by a “separate system clock generator for the microprocessor 2.” (<i>Appendix D, col. 4, lines 34-38</i>). It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator in a different embodiment. The microprocessor operates at the frequency of the oscillator.
said variable speed clock being constructed of a second plurality of transistors;	<p>One skilled in the art would understand the on-chip oscillator circuit and the main control logic to include a plurality of transistors.</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that all CPUs and clocks inherently include a plurality of transistors.</p>
clocking said central processing unit at a clock rate using said variable speed clock with said central processing unit being clocked by said variable speed clock	Richter teaches that a “voltage-controlled oscillator generates a clock pulse ‘ftakt’ that acts upon the microprocessor system.” (<i>Appendix D, col. 3, lines 18-20</i>). In some embodiments the ‘ftakt’ signal is used as both the system clock and a clock for the I/O port. (<i>Appendix D, col. 4, lines 34-43</i>). In other embodiments Richter teaches that the microprocessor is clocked by a “separate system clock generator for the microprocessor 2.” (<i>Appendix D, col. 4, lines 34-38</i>). It is inherent to use a second, voltage controlled oscillator as the separate system clock generator because Richter already teaches clocking the microprocessor with a voltage controlled oscillator in a different embodiment. The microprocessor operates at the frequency of the oscillator.
at a variable	Richter teaches implementing the microprocessor “in a one-chip system.”

Claim Limitation	Teaching of the Richter Reference
<p>frequency dependent upon variation in one or more fabrication or operational parameters associated with said integrated circuit substrate, said processing frequency and said clock rate varying in the same way relative to said variation in said one or more fabrication or operational parameters associated with said integrated circuit substrate;</p>	<p>(<i>Appendix D, col. 2, lines 55-65</i>), which would necessarily be constructed by a single process technology. This indicates that the oscillator is fabricated on the same chip as the CPU and that the oscillator and CPU would therefore be constructed by the same process technology. (<i>Appendix F, page III-114</i>)</p> <p>It is noteworthy that the Patent Owner has stated in correspondence to various third parties that the features of this limitation are inherent in an integrated circuit with a CPU and a clock (the Office is urged to require Patent Owner to produce this correspondence under Rule 105). As one specific example, the Patent Owner has stated that because of “the laws of physics and the state of the art of microprocessor manufacturing, the processing frequency of said central processing unit and the speed of the ring oscillator, because they are located on the same integrated circuit, vary together due to manufacturing variations, operating voltage and temperature.” (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 13 at 6</i>).</p> <p>Further, during the examination of the ‘336 patent, the Applicant stated that “the placement of [the ring oscillator clock and the microprocessor] within the same integrated circuit” causes the microprocessor and clock to naturally “vary commensurately in speed as a function of various parameters (e.g., temperature) affecting circuit performance.” (<i>Appendix B, April 15, 1996 Applicant Arguments, original page 6.</i>)</p> <p>As an aside, Requestor notes that this feature was commonplace at the time of filing, as shown by U.S. Patent No. 4,691,124 to Ledzius et al. Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in process variations throughout the circuit. (<i>Appendix I, col. 4, lines 11-12</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the processor of Richter with minimal cost and defects.</p> <p>Ledzius teaches that manufacturing circuits from the “same batch and section of semiconductor wafer” results in frequency variations due to process and temperature variations throughout the circuit. (<i>Appendix I, col. 4, lines 3-21</i>). Richter contemplates providing all the chips required for the microprocessor’s functioning on a “one-chip system.” (<i>Appendix D, col. 2, lines 59-66</i>). One skilled in the art would have found an apparent reason to combine Ledzius with Richter, namely to produce the one-chip system of Richter with minimal cost and defects.</p>
<p>connecting an on chip input/output interface between said central</p>	<p>Richter teaches that the “microprocessor system 2 has a serial interface (not shown) which is connected by the input/output port 7 to a signal line 8 of the serial bus system 6.” (<i>Appendix D, col. 2, lines 55-58</i>).</p>

Claim Limitation	Teaching of the Richter Reference
processing unit and an external memory bus, and exchanging coupling control signals, addresses and data between said input/output interface and said central processing unit; and	Richter teaches that the serial interface is connected to other microprocessor systems which contain various types of memory. (<i>Appendix D, col. 2, lines 32-68</i>).
clocking said input/output interface using an external clock wherein said external clock is operative at a frequency independent of a clock frequency of said variable speed clock.	<p>Richter teaches a signal “ftakt” for clocking the serial I/O port of the microprocessor that is independent of the CPU clock: “the data transmission of the serial interface is supplied with the clock frequency signal ‘ftakt’, and the microprocessor of the microprocessor system 2 is equipped with its own system clock generator.” (<i>col. 4, lines 34-43 and 58-62</i>) Richter describes the system clock as a “separate system clock generator for the microprocessor” that is independent of the I/O clock signal. (<i>col. 4, lines 36-47</i>)</p> <p>Additionally, the Patent Owner has stated in correspondence to various third parties that any serial interface satisfies the limitation of a second independent clock. (<i>Reexamination Control Number 90/008,306, Original Ex Parte Request by Third Party, Exhibit 12 at 7-8</i>). As previously described, Richter clearly teaches a serial interface. If the Patent Owner’s assertions are true today as to commercial processors, then they are also true as to the prior art processors.</p> <p>In any case, Requestor notes that the use of a second independent clock for providing clocking signals to an I/O interface was commonplace at the time of filing. (<i>See, e.g., US Patent Nos. 4,443,845 (col. 17, lines 1-42; figs. 14A-14B); 4,409,665 (col. 5, lines 46-6, lines 41; fig. 3c); 4,053,946 (col. 34, lines 15-31); 4,868,784 (col. 25, Table I, “Serial-clock control”); 5,142,637 (col. 6, line 59 to col. 7, line 5; col. 7, line 63 to col. 8, line 2; Figs. 12 & 13)</i>).</p>

From the foregoing chart, it can be seen that claims 1-10 are anticipated and rendered obvious by the Richter reference. Thus, claims 1-10 are unpatentable as being anticipated under 35 U.S.C. § 102(b) and or obvious under U.S.C. § 103.

E. The Richter Reference Anticipates or Renders Obvious the Newly Introduced Claims of the '336 Patent

The Richter reference anticipates or renders obvious new claims added during the patent's ongoing merged reexamination. Specifically, the Patent Owner added claims 11-20 which parallel respective original claims 1-10 except that they further include a limitation to "more clearly set forth the meaning of 'independent.'" (*Appendix C, Amendment, Sept. 8, 2008, original page 11*). The additional limitation appends the parallel independent claims and recites: "thereby enabling decoupling a speed of said central processing unit from a speed of said input/output interface." (*Id.*)

Richter teaches an embodiment where the clock for the serial interface and the speed of the serial interface is distinct from a "separate system clock generator for the microprocessor 2." (*Appendix D, col. 4, lines 34-38*). This separate system clock would not be tied to the serial interface and thus provides a decoupling of speed of the microprocessor from the serial interface.

XI. CONCLUSION

For the foregoing reasons, substantial and new questions of patentability have been raised with respect to all claims 1-10 of the '336 patent. The Mostek, Dozier, and Richter references anticipate or render obvious, either alone or in combination with other references as described in the foregoing charts, each of the claims of the '336 patent. The questions of patentability presented herein are new even with respect to the pending reexamination proceedings.
